Richard Clay and Sons, Limited,
London and Bungay.

# INDEX

ABBE (Prof. C.), the History of Modern Weather Prediction, 499
Abbott (Dr. G.), on the Concretionary Structures of the Magnesian Limestone of Durham, 587
Aberdeenshire, West, on the Physical Character of the Population of, J. Gray, 635-6
Abney (Sir William), Colour Photometry (iii), 273
Abruzzi (Duke of), the Ascent of Mount St. Elias, Alaska, 1, 529
Abt (A.), Thermoelectric Force of some Metallic Oxides and Sulphides, 335
Academies, the International Association of, 249
Acetylene: The Purification of Acetylene, 110; a Handbook for the Student and Manufacturer, Vivian B. Lewes, 522
Achard (Ch.), Anti-coagulating Power of Serum in Pathological State, 216
Ackroyd (W.), on the Distribution of Chlorine in West Yorkshire and on the Limiting Standard of Acidity for Moorland Waters, 566
Acland (Sir H. W. D., F.R.S.), Death of, 602; Obituary Notice of, 627
Acoustics: an Illustration of Doppler's Principle, Prof. R. Richarz, 35; a New Instrument to Measure and Record Sounds, Dr. Benjamin F. Sharpe, 80; the Photography of Sound Waves, Prof. R. W. Wood, 342; the Distance to which the Firing of Heavy Guns is Heard, Dr. Charles Davison, 377; J. W. Mallet, 523; High Note Production by Galton's Whistle, M. T. Edelmann, 381; Acoustical Triangulation, A. J. Mundy, 422; New Effect produced by Stationary Sound-waves, R. Davis, 568
Acquisition of Language, Homochronous Heredity and the, Prof. R. Meldola, F.R.S., 572
*Acrospeira mirabilis*, on the Life History of, R. H. Biffen, 613
Action of Water upon Glass, the, Edmund F. Mondy, 246
Adams (Prof. F. D.), the Flow of Marble, 335
Aëronautics: the Mechanics of Flight, Lord Rayleigh, 108; Count von Zeppelin's Navigable Balloon, 180, 231, 396; Count Zeppelin's Air-ship, 626
Aether and Matter, Joseph Larmor, Prof. Geo. Fras. Fitzgerald, F.R.S., 265
Aflalo (F. G.), a Walk through the Zoological Gardens, 466
Africa: Preliminary Notes on the Results of the Mount Kenya Expedition 1899, H. J. Mackinder, 12; Spider-silk manufacture in Madagascar, M. Nogue, 17; Grandidier's Expedition to Madagascar, 35; the Winds of Kimberley, J. R. Sutton, 35; a New Edible Tuber from the Soudan, Maxime Cornu, 72; a Possible Prevention of Horse-sickness, Dr. G. C. Purvis, 83; the Cape Colony Fruit-moth, Mr. Barrett, 119; Death and Obituary Notice of Miss M. H. Kingsley, 134; Locust Destruction, W. C. Robbins, 134; the Carboniferous Strata of Nossi-Bé, M. Villiaume, 168; Effect on Lower Nile of "Sudd" Cutting on Upper Nile, 180; Palæolithic Man in Africa, Sir John Evans, F.R.S., 190; South African Philosophical Society, 216, 264, 464; Sette Anni di Caccia Grossa é Note di Viaggio in America, Asia, Africa, Europa, Count Felice Scheibler, 244: Theriodont Reptile from Baviaans River, Cape Colony, Prof. H. G. Seeley, F.R.S., 262; the Snake-stone, E. H. L. Schwarz, 302; Bushman Drawings, E. H. L. Schwarz, 336; Mud Island in Walfisch Bay, 336; Mr. Cleverly, 464; Ghizeh Zoological Gardens, 374; Change of Feeding Habits of Rhinoceros-birds in British East Africa, Prof. E. Ray Lankester, F.R.S., Capt. Hinde, 366; the White Rhinoceros on the Upper Nile, Oldfield Thomas, 599; Neogenic Regions of Lower Egypt, C. Depéret and R. Fourtau, 408; the Ndonda District, H. A. Byatt, 422; Palæolithic Implements from Stellenbosch, L. Péringuey and G. S. Corstophine, 464; Egyptian Gold, Daniel Berthelot, 464; the Fauna of South Africa, Mammals, W. L Sclater, 521; the Preservation of Big Game in Africa, E. N. Buxton, 550; Report of the British Association Committee on the Climate of Tropical Africa, 590; Proof of old Semitic Influence in South Africa, K. Meinhof, 606
Agamennone (Dr. G.), the Action of Horizontal and Vertical Pendulums in Seismography, 62
Age of the Earth, the, Prof. Eugene Dubois, 498; the Geological Age of the Earth, J. Joly, F.R.S., 235
Agnosticism, Naturalism and, James Ward, 25
Agriculture: Irrigation and Drainage, F. H. King, 5; the Farmstead, Prof. J. P. Roberts, 53; Strontium and Barium unfit to replace Calcium in Phanerogams, Dr. U. Suzuki, 136; the Destruction of the "Moth-borer" Caterpillar, 182; Rural Wealth and Welfare, Geo. T. Fairchild, 245; "Frost Fighting," A. G. McAdie, 274; Solubility of Calcium Phosphate in Soil Water in Presence of Carbon Dioxide, Th. Schloesing, 312; Recent Investigations on Rust of Wheat, William G. Smith, 352; Michigan Board of Agriculture, Annual Report, 1898-99, 365. Agricultural Chemistry: Death of Sir John Bennet Lawes, Bart., F.R.S., 456; Obituary Notice of, Prof. R. Warington, F.R.S., 467; Agricultural Botany, John Percival, 570; Year-book of the United States Department of Agriculture, Prof. R. Warington, F.R.S., 597; Further Investigations of Xenia in Maize, Herbert J. Webber, 601; the Bobolink as a Rice Pest, F. E. L. Beal, 605
Ainu *inao*, on the Japanese *Gohei* and the, W. G. Aston, 635
Air: the Carbonic Anhydride of the Atmosphere, Prof. E. A. Letts, R. F. Blake, 387; the Air of Rooms, Francis Jones, 387
Air, Water and Food, Ellen H. Richards, Alpheus G. Woodman, 620
Aitken (John, F.R.S.), Dynamics of Cyclones and Anticyclones, ii., 95; Atmospheric Electricity, 366
Aitken (R. G.), New Planetary Nebula, 606; New Double Stars, 630
Alaska, the Ascent of Mount St. Elias, Duke of Abruzzi, 1, 529
*Albatross* in the Pacific, Explorations of the, 307
Albatross, Tenacity of Life of the, Prof. John Perry, F.R.S., 621; Captain Wm. J. Reed, 621
Albinism and Natural Selection, Walter Garstang, 620
Alexander (W. B.), the Climate of St. Christopher, 35
Algæ, Codium, 63
Algebra, Machine for Solving Algebraic Equations, Georges Meslin, 253
Algeria: Vinification dans les Pays Chauds—Algérie et Tunisie, J. Dugast, 74
Allbutt (Prof. T. C., F.R.S.), Historical Aspects of the Discovery of the Circulation of the Blood, 630
Allchin (J. H.), a Swallow-cum-Sparrow Nest, 532
Allen (J. A.), the Wood Bison, 35
Allingham (William), A Manual of Marine Meteorology, 268
Alloys: Heat of Formation, J. B. Tayler, 70; Want of Uniformity of Action of Copper-zinc Alloys on Nitric Acid, Dr. J. H. Gladstone, 70; Properties of Gold and Copper Alloys, Prof. Sir W. C. Roberts-Austen, F.R.S., and T. K. Rose, 93; the Solidification of Alloys, Fred. T. Trouton, F.R.S., 523

*Alnus Glutinosa*, on the Structure of the Root-nodules of, T. W. Woodhead, 613
Alpine Tunnels, the Great, Francis Fox, 281
Althaus (Dr. Julius), Death of, 157
Amateur's Practical Garden Book, the, C. E. Hunn, L. H. Bailey, 101
Amdrup Arctic Expedition, Return of, 577
America: La spedizione di sua Altezza Reale il Principe Luigi Amadeo di Savoia, Duca degli Abruzzi al Monte Sant' Elia (Alaska), 1897, Dottore Filippo de Filippi, 1., 529; the Highest Andes, E. A. Fitzgerald, Edward Whymper, 38; Bulletin of American Mathematical Society, 69, 189, 260, 381; Transactions of American Mathematical Society, 260, 519; American Journal of Mathematics, 92, 381; American Journal of Science, 92, 210, 286, 432, 568, 638; Our Native (American) Birds, D. Lange, 100; the Geography of the Region about Devil's Lake and the Dalles of the Wisconsin, Prof. R. D. Salisbury, W. W. Atwood, 172; Sette Anni di Caccia Grossa é Note di Viaggio in America. Asia, Africa, Europa, Count Felice Scheibler, 244; the New York Meeting of the American Association, 269; Maryland Weather Service, 292; American Institute and English Institution of Electrical Engineers at Paris, 415; Missouri Botanical Garden, Eleventh Annual Report, 495
Amsterdam Royal Academy, 47
Amsterdam Royal Society, 96
Analytical Chemistry, an Introduction to, G. G. Henderson, M. A. Parker, 292
Analytical Portraiture, Francis Galton, F.R.S., 320; Photographic side of Mr. F. Galton's Suggestions, 374
Anatomy: Death of Prof. G. V. Ellis, 16; Erinnerungen aus meinem Leben, A. Kölliker, 169; Death of Dr. Karl Lange, 198; Death and Obituary Notice of Prof. Corrado Tommasi-Crudeli, 228; Handbuch der Anatomie und Vergleichenden Anatomie des Centralnervensystems der Säugetiere, Dr. Edward Flatau, Dr. L. Jacobsohn, 267; Morphological Anatomy of Vertebrates; the Air-chambers in Mammalian Skull, Dr. S. Paulli, 323; the Brain of the Pond-Tortoise, Dr. B. Haller, 324; an Introduction to the Study of the Comparative Anatomy of Animals, G. C. Bourne, 364; Descriptive and Illustrated Catalogue of the Physiological Series of Comparative Anatomy contained in the Museum of the Royal College of Surgeons of England, 385; Genesis of the Vertebrate Column, Herbert Spencer, 620
Ancient Records of Meteor Showers, M. D. Eginitis, 203
Anderson (Dr. John, F.R.S.), Death of, 394; Obituary Notice of, 529
Anderson (Prof. R. J.), Crooked-Keeled Breast-bone in Fowls, 159
Anderson (Dr. T. D.), New Variable in Auriga, 161
Andes, the Flora of the, H. H. W. Pearson, 46
Andes, the Highest, E. A. Fitzgerald, Edward Whymper, 38
André (Ch.), Apparent Semi-diameter of Sun, 464
André (G.), Action of Sulphur Dioxide and Hydrogen Sulphide on Pyridine, 216
Andrews (C. W.), a Monograph of Christmas Island (Indian Ocean), Physical Features and Geology, 193
Andrews (William), the Migration of Swifts, 436
Anemometer Tests, Prof. C. F. Marvin, 280
*Angiopteris Evecta*, on the Structure of the Stem of, Miss R. F. Shove, 612
Animal Cults of the Natives of Sarawak, on the, and their Bearing on the Problems of Totemism, Dr. C. Hose, W. McDougall, 634; Mr. Hartland, 635
Animals, an Introduction to the Study of the Comparative Anatomy of, G. C. Bourne, 364
Annalen der Physik, 92, 211, 338, 381, 568, 639
Annandale (N.), on the Appearance and Habits of Some Malay Insects, 590
Ant, Red, Web-spinning habits of, E. G. Green, 253
Antarctica: Magnetic Observations during *Belgica* Expedition, 108; *Racovitza Glacialis*, new Antarctic fish, Louis Dollo, 350; the Antarctic Regions, Dr. Karl Fricker, Dr. Hugh Robert Mill, 624; Through the First Antarctic Night, 1898–99, Frederick A. Cook, Dr. Hugh Robert Mill, 624
Antelopes and their Recognition Marks, R. I. Pocock, 584
Anthills, Artificial, at Paris Exhibition, C. Janet, 490
Anthropology: the Races of Europe, a Sociological Study, William Z. Ripley, Prof. A. C. Haddon, F.R.S., 27; Death of Lieut.-Gen. Pitt-Rivers, F.R.S., 33; Obituary Notice of, 59; Dugong Vertebra as bracelet in Pelew Islands, Dr. O. Finsch, 36; Decorative Art of Sea Dayaks of Sarawak, Prof. A. C. Haddon, F.R.S., 68; Genealogical Researches in Torres Straits, Dr. W. H. R. Rivers, 71; Anthropological Institute, 71, 119, 167, 190; Stone Implements from Pitcairn Islands, J. Allen Brown, 119; Malay Magic, W. W. Skeat, 145; Earliest Communications between Italy and Scandinavia, Prof. O. Montelius, 167; Original Character of the British People, Nottidge Charles Macnamara, 172; the English Metric System of Criminal Identification, Dr. J. G. Garson, 190; Human Babies: what they Teach, S. S. Buckman, 221; the White Huns, C. de Ujfalvy, 323; Bushman Drawings, E. H. L. Schwarz, 336; Craniology of Irano-Indians, M. Ujfalvy, 351; Memorial Notices of F. H. Cushing, 397; Artificial Deformation of Heads and some Customs connected with Polyandry, Kumagusu Minakata, 437; Palæolithic Implements from Stellenbosch, L. Péringuey and G. S. Corstophine, 464; the Ginn in Morocco, Dr. E. Westermarck, 499; Slavic Skull at Niedersedlitz, Prof. J. Deichmüller, 533; Mexican Symbolism, Carl Lumholtz, Prof. Alfred C. Haddon, 600; the Peopling of Australia, Sidney H. Ray, 621; Annual Congress of the German Anthropological Society, 632; *see also* Section H of the British Association
Antoniadi (E.), Anomaly of Dichotomous Phase of Venus, 464
Applications of Electrical Science, Prof. G. F. Fitzgerald, 43
Aquila, New Star in, 305
*Araucarioxylon*, on the Primary Structure of Certain Palæozoic Stems Referred to, Dr. D. H. Scott, F.R.S., 612
Arber (E. A. Newell), on the Effect of Salts on the $CO_2$ Assimilation of *Ulva latissima*, 611
Archæology: Pompeii and its Remains, 7; the Alleged Buddha Relics, 200; Indian Burial Caves on Rio Cunany, Brazil, Dr. Goeldi, 500; the Recent Cretan Discoveries and their bearing on the Early Culture and Ethnography of the East Mediterranean Basin, Arthur J. Evans, 526; *see also* Section H of the British Association
Archibald (E. D.), Indian Famine-causing Droughts, 335
Arctica: the Norwegian North Polar Expedition 1893–1896 to Franz Josef Land, Scientific Results, Fridtjof Nansen, J. F. Pompeckj, A. G. Nathorst, R. Collett, 146; the Russian Expedition at Spitsbergen, 373; Return of Amdrup Expedition, 577; Musk Ox to be Acclimatised in Sweden, 577
Ardnamurchan, on a Granophyre Dyke Intrusive in Gabbro at, Prof. K. Busz, 588
Argyll (the Duke of), Death and Obituary Notice of, 13
Arithmetic: Elements de la Théorie des Nombres, E. Cohen, 52
Arizona, "Chalcedony Park," the, L. F. Ward, 62
Armitage (Mrs.), on some Yorkshire Earthworks, 637
Armstrong (Prof.), Dr. Lodge's Paper on Volta's Contact Force, 70; Inhibiting Effect of Etherification on Substitution in Phenols, 261; Ions, 564
Arnold (Mr.), Relative Advantages of Alternate and Continuous Current for General Electrical Supply, with regard to interference with other interests, 415
Arons (L.), Electric Arc between Metallic Electrodes in Nitrogen and Hydrogen, 93
Art and Industry, Science in Relation to, 32
Art, Medicine as a Science and Medicine as an, Dr. P. H. Pye-Smith, F.R.S., 356
Asbestos, Physical Structure of, Geoffrey Martin, 369
Ascent of Sap, Dr. Henry H. Dixon, Prof. J. Joly, F.R.S., 572
Aschan (Prof. Ossian), on the Constitution of Camphor, 567
Asia: Sette Anni di Caccia Grossa e' Note di Viaggio in America, Asia, Africa, Europe, Count Felice Scheibler, 244; Babylonians and Assyrians, Life and Customs, Rev. A. H. Sayce, 289
Aspen Leaf, the Trembling of the, Henry J. Colbourn, 436
Association of German Naturalists and Physicians, 553
Assyria: the Reports of the Magicians and Astrologers of Nineveh and Babylon, R. C. Thompson, 5; Babylonians and Assyrians, Life and Customs, Rev. A. H. Sayce, 289
Aston (W. G.), on the Japanese *Gohei* and the Ainu *inao*, 635
Astrographic Chart Conference, the, 377
Astrology, the Reports of the Magicians and Astrologers of Nineveh and Babylon, R. C. Thompson, 51
Astronomy: the Nature of the Solar Corona, Prof. Geo. Fras. Fitzgerald, F.R.S., 7; Photometry of Corona, April 16, 1893, Prof. H. H. Turner, 86; Proportion of Polarised Light in Solar Corona, J. J. Landerer, 167; Polarisation of Solar Corona observed at Elche, P. Joubin, 191; Automatic

Photography of the Corona, Prof. C. Burckhalter, 535 ; Our Astronomical Column, 19, 37, 64, 86, 110, 137, 160, 183, 202, 233, 256, 304, 324, 352, 377, 398, 425, 459, 491, 501, 535, 556, 581, 606, 630 ; New Variable in Taurus, Madame Ceraski, 19 ; Relation between Solar Activity and Earth's Motion, W. G. Thackeray, 20 ; Determination of Solar Parallax from Opposition of Eros, Prof. S. Newcomb, 20 ; Ephemeris for Eros, 20, 110, 184, 233, 377, 459 491, 501, 535, 556, 581, 606, 630 ; Photographic Observations of Eros, Prof. Howe, 137 ; Howe's Photographic Observation of Eros, A. C. D. Crommelin, 184 ; Measures of Eros, 233 ; Opposition of Eros, Prof. S. J. Brown, 425 ; M. Loewy, 630 ; Astronomical Application of Physical Problem Investigated at Solar Physics Observatory, Sir Norman Lockyer, 23 ; Comet Giacobini (1900 *a*) 37, 256 ; Colour Screens for Refracting Telescopes, T. J. J. See and G. H. Peters, 37 ; Photometric Revision of Harvard Photometry, 37 ; the Total Eclipse of the Sun, 54, 132, 398 ; Charles P. Butler, 54 ; Sir Norman Lockyer, K.C.B., F.R.S., 104 ; M. Deslandres, 233 ; a French Observation of the Total Eclipse of the Sun, 183 ; the Total Eclipse Observed at Sea, Col. E. E. Markwick, 183 ; the Total Solar Eclipse as Observed by the Smithsonian Expedition, 246 ; Maximum Duration of a Total Solar Eclipse, C. T. Whitmell, 64, 86 ; Duration of Totality of Solar Eclipses at Greenwich, Chas. T. Whitmell, 269 ; the Dark Fringes Observed during Total Solar Eclipses, V. Ventosa, 86 ; Actinometric Observations during Solar Eclipse of May 28, 1900, J. Violle, 216 ; S. R. Bennett, 263 ; the Solar Eclipse of May 28, Prof. Copeland and Thomas Heath, 263 ; Eclipse Photography, Prof. Francis E. Nipher, 246 ; the Next Total Eclipse of the Sun, 202 ; the Total Eclipse of the Sun of May 17–18, 1900, J. J. A Muller, 389 ; Unpublished Observations at Radcliffe Observatory, 1774–1838, Dr. A. A. Rambaut, 64 ; Rotation of Jupiter and his Spots, Th. Bredikhin, 70 ; the Spectrum of β-Lyræ and η-Aquilæ, A. Belopolsky, 70 ; Zenitho-nadiral Apparatus for Measuring Zenithal Distances of Stars near Zenith. A. Cornu, 95 ; Astronomical Occurrences in June, 110 ; in July, 202 ; in August, 304 ; in September, 425 ; in October, 535 ; Oxford University Observatory, Prof. H. H. Turner, 110 ; Rousdon Observatory, Devon, Sir C. E. Peek, 110 ; Occultation of Saturn, 137 ; Harvard College Observatory, 137 ; Liverpool Observatory, W. E. Plummer, 137 ; Temperature Control of Spectrograph, Prof. W. W. Campbell, 137 ; Rotation Period of Venus, Prof. A. Belopolsky, 160 ; Jeremiah Horrocks and the Transit of Venus, 257 ; Anomaly of Dichotomous Phase of Venus, E. Antoniadi, 464 ; New Variable in Auriga, Dr. T. D. Anderson, 161 ; Photographic Observations of Satellite of Neptune, M. S. Kostinsky, 161 ; the Perseid Meteoric Shower, W. F. Denning, 173 ; the August Perseids of 1900, W. F. Denning, 398 ; Ancient Records of Meteor Showers, M. D. Eginitis, 203 ; Meteor of July 17, 305 ; Meteoric Theory of the Gegenschein, F. R. Moulton, 305 ; Velocities of Meteors, Dr. W. L. Elkin, 398 ; the Daylight Meteor of Sunday, September 2, W. F. Denning, 491 ; T. Rooke, 524 ; B. H. G. Lefroy, 524 ; the Fireball of Sunday, September 2, 535 ; the Stability of a Swarm of Meteorites and of a Planet and Satellite, Prof. A. Gray, F.R.S., 582 ; New Variable Star in Cepheus, Madame Ceraski, 183 ; the Kinetic Theory of Planetary Atmospheres, Prof. G. H. Bryan, F.R.S., 189 ; the Royal Observatory, Greenwich, 233 ; Notes on Saturn and his Markings, W. F. Denning, 237 ; Occultations of Saturn, 425 ; Rhythms and Geologic Time, G. K. Gilbert, 275 ; New Variable in Herculis, Madame Ceraski, 305 ; New Star in Aguila, 305 ; Comet Borrelly-Brooks, 1900 *b*, 324, 352, 377, 535 ; G. Rayet and A. Férand, 464 ; Catalogue of Double Stars, Prof. S. W. Burnham, 324 ; Ephemeris of Comet 1894 IV. (Swift), 352 ; Comet Swift (1894 IV.), 459 ; Variable Stars in Clusters, 352 ; the Astrographic Chart Conference, 377 ; Determination of Solar Parallax, 377 ; Observations of Stars, Capella as Double Star, W. H. M. Christie, 383 ; Report of the Cape Observatory, Sir David Gill, 398 ; Rousdon Observatory (Devon), Variable Stars, T Cassiopeiæ and R Cassiopeiæ, Sir C. E. Peek, 398 ; Independent Day Numbers for 1902, 398 ; Standards for Faint Stellar Magnitudes, 398 ; Ring Nebula in Lyra, 425 ; Orientation of the Field of View of the Siderostat and Cœlostat, A. Fowler, 428 ; Death of Prof. J. E. Keeler, 456 ; Obituary Notice of, 497 ; the New Spectrographs for the Potsdam Great Refractor, Prof. H. C. Vogel, 459 ; Structure and Composition of Two New Meteorites, G. P. Merrill, H. N. Stokes, 459 ; Latitude Variation, Earth Magnetism and Solar Activity, Dr. J. Halm, 460 ; Apparent Semi-Diameter of Sun, Ch. André and Ph. Lagrula, 464 ; Swift's Comet (1892 I.), Prof. W. Pickering, 501 ; Astronomischer Jahresbericht, W. F. Wislicenus, 553 ; a Night with the Great Paris Telescope, C. P. Butler, 574 ; New Planetary Nebula, R. G. Aitken, 606 ; Paris Observatory Annual Report, M. Loewy, 606 ; New Double Stars, R. G. Aitken, 630 ; Astronomical Work at Daramona Observatory, W. E. Wilson, 630
Astrophysics : Escape of Gases from Planetary Atmospheres, S. P. Cook, 54 ; Dr. G. Johnstone Stoney, F.R.S., 78 ; Comets and Corpuscular Matter, F. H. Loring, 80
Atkinson (Dr. Edward), Death and Obituary Notice of, 34
Atkinson (Prof. George F.), Lessons in Botany, 30
Atlantic Ocean, North, on the Weather of the, during the Winter 1898–9 ; Captain Campbell Hepworth, 563
Atlas of Urinary Sediments, Dr. Hermann Riedel, 53
Atmosphere, the Carbonic Anhydride of the, Prof. E. A. Letts, R. F. Blake, 387
Atmospheres, Planetary, the Kinetic Theory of, Prof. G. H. Bryan, F.R.S., 126
Atmospheric Electricity, C. T. R. Wilson, 149 ; John Aitken, F.R S., 366
Atmospheric Electricity and Dew-ponds, Arthur Marshall, 495
Atmospheric Resistance, Specially built Train for Experiment on, 200
Atmospherical Circulation, Dynamical Theory of, Prof. V. Bjerknes, 200
Atwater (Prof. W. O.), Dietary Studies of Harvard and Yale University Boat Crews, 232
Atwood (W. W.), the Geography of the Regions about Devil's Lake and the Dalles of the Wisconsin, 172
Auerbach (F.), Hardness of Metals, 639
August Perseids of 1900, the, W. F. Denning, 398
Auriga, New Variable in, Dr. T. D. Anderson, 161
Australia : a Key to the Birds of Australia and Tasmania, with their Geographical Distribution in Australia, R. Hall, 6 ; Fungus Diseases of Citrus Trees in Australia and their Treatment, D. McAlpine, 494 ; Catalogue of Eastern and Australian *Lepidoptera Heterocera* in the Collection of the Oxford University Museum, 548 ; the Peopling of Australia, John Mathew, 549 ; Sidney H. Ray, 621
Automatic Photography of the Corona, Prof. C. Burckhalter, 535
Automobile Trials at Paris Exhibition, 158
Automobiles, the Musker Steam Motor Waggon, 554
Autotomic Curves, A B. Basset, F.R.S., 572
Autumn Tints, Leaf Decay and, P. Q. Keegan, 523
Ayrton (Prof. W. E., F.R.S.), Electrical Power Distribution, 296 ; a Recollection of King Umberto, 320 ; Relative Advantages of Alternate and Continuous Current for General Electrical Supply, with regard to Interference with other interests, 416

Babies, Human, What they Teach, S. S. Buckman, 221
Babylon, the Reports of the Magicians and Astrologers of Nineveh and, R. C. Thompson, 51
Babylonians and Assyrians, Life and Customs, Rev. A. H. Sayce, 289
Bacchus (Ramsden), the Forthcoming Meeting of the British Association at Bradford, 156, 300, 392, 439
Bacteriology : the Principles of Bacteriology, Dr. Ferdinand Hueppe, Dr. A. C. Houston, 73 ; Bacteriological Method of Exterminating Rats, J. Danysz, 84 ; the Bacterial Treatment of Sewage, Dr. Frank Clowes, Dr. Houston, 128 ; Micro-Organisms and Fermentation, Alfred Jörgensen, 195 ; Influence of Temperatures of Liquid Hydrogen on Bacteria, Allan Macfadyen and Sydney Rowland, 286 ; Bacillus Anthracis Brevigemmans, C. Phisalix, 408 ; Living Light, Raphael Dubois, 464 ; the Structure and Functions of Bacteria, Alfred Fischer, Dr. A. C. Houston, 465 ; Tobacco, 576 ; the Melbourne University Laboratory, 578
Baeyer (Herr), the New Hydride of Benzoyl Superoxide, 202 ; the Action of Permanganate on Hydrogen Peroxide, 629
Bailey (Dr. G. H.), Elements of Qualitative Analysis, 412
Bailey (L. H.), the Amateur's Practical Garden Book, 101
Bailey (V.), Field-mice (North American Voles), 232
Baily (Prof. F. G.), on a Lecture-room form of Volt and Ammeter, 563

Baker (R. J.), New Meteorite from New South Wales, 384

British Association, the Bradford Meeting of the, Preliminary Arrangements, 369; Ramsden Bacchus, 156, 300, 392, 439; Inaugural Address by Prof. Sir William Turner, F.R.S., President of the Association, 440; Report on the Proceedings in Section A, Mathematics, E. T. Whittaker, 561; Report on the Proceedings in Section A, Physics, Dr. C. H. Lees, 562; Report on the Proceedings in Section A, Astronomy, A. Fowler, 565

*Section A* (*Mathematics and Physics*).—Opening Address by Joseph Larmor, F.R.S., President of the Section, 449; Report of the Committee for Calculating Tables of certain Mathematical Functions, 561; Report of Miss F. Hardcastle on the Present State of the Theory of Point Groups, 561; Major MacMahon on a Property of the Characteristic Symbolic determinant of any *n* quantics in *n* variables, 561; Prof. Cyparissos Stephanos sur les Relations entre la Géometrie Projective et la Mecanique, 561; Mr. H. S. Carslaw on the Use of Multiple Space in Applied Mathematics, 561; Lieut.-Colonel Cunningham and Mr. H. J. Woodall on the Determination of Successive High Primes, 561; Dr. J. Willis on the Construction of Magic Squares, 561; Major MacMahon on the Asyzygetic and Perpetuant Co-variants of systems of Binary Quantics, 561; Major MacMahon on the Symbolism appropriate to the study of Orthogonal and Boolian Invariant Systems which appertain to Binary and other Quantics, 561; Mr. A. B. Basset, F.R.S., on the result that a Quintic Curve cannot have more than Fifteen Real Points of Inflexion, 561; Dr. Trouton on the Creeping of Liquids and on the Surface Tension of

Mixtures, 562; Prof. G. H. Bryan on the Partition of Molecular Energy, 562; Prof. Fitzgerald, 562; Dr. Larmor on the Results of his Application of the Principle of Least Action to the Statistical Dynamics of Gas Theory, as illustrated by Meteor Swarms and Optical Ray Systems, 562; Report of the Seismological Committee, 562; Dr. Larmor on the Relation of Radiation to Temperature, 562; Prof. Fitzgerald, 562; Dr. S. P. Langley's Chart of the Infra-red Spectrum from $\cdot 7$ to $5\cdot 3\mu$ obtained by the Bolometric Method, 562; Report of the Committee on Meteorological Phenomena, 562; Report of the Committee on Solar Radiation on Experiments by Prof. Callendar on the Modified Copper-cube Actinometer, 562; Mr. A. S. Davies on a Novel Form of Mercurial Barometer, 562; Mr. A. L. Rotch on the Use of Kites for Meteorological Observations, 563; Captain Campbell Hepworth on the Weather of the North Atlantic Ocean during the Winter 1898-9, 563; Mr. J. W. Thomas on the Physical Effects of Wind in Towns and their Influence upon Ventilation, 563; Mr. J. Hopkinson on the Rainfall of the Northern Counties of England, 563; Mr. G. E. Petaval's Apparatus for Experiments on the Explosive Pressures of Gases, 563; Mr. J. W. Gifford's Quartz-calcite Lens with Identical Visual and Photographic Focus, 563; Messrs. A. Dufton and W. M. Gardner's Arrangement for producing Artificial Light of the same Character as Daylight, 563; Mr. H. Ramage's Method of Investigating Correspondences between Spectra, 563; Mr. G. J. Burch's Experiment on Simultaneous Contrast, 563; Report of the Committee for improving the Method of Determining Magnetic Force on Board Ship, 563; Report of the Committee on Radiation in a Magnetic Field, 563; Report of the Electrical Standards Committee on the Removal of the Standards to Kew, 563; Mr. R. S. Whipple's Improved Standard Resistance Coils, 563; Mr. E. H. Griffith's Form of Wheatstone Bridge for Determining the Freezing-points of Dilute Solutions by Platinum Thermometry, 563; Mr. R. Threlfall, 563; Prof. F. G. Baily on a Lecture-room Form of Volt- and Ammeter, 563; Prof. W. B. Morton's Results obtained by applying J. J. Thomson's and Sommerfeld's Solution of the Propagation of an Electric Wave along a Single Wire, 563; Mr. S. H. Burbury on the Vector Potential of Electric Currents in a Field where Disturbances are propagated with Finite Velocity, 563; Sir William H. Preece on Wireless Telegraphy, 564; Prof. G. F. Fitzgerald on Crémieu's Experiment, 564; Dr. J. Larmor, 564; Prof. J. Chunder Bose on the Effect of Electrical Stimulus on Inorganic and Organic Substances, 564; Report of the Committee on Electrolysis and Electrical Chemistry, 564; Prof. G. F. Fitzgerald on Ions, 564; Dr. J. Larmor, 564; Prof. H. E. Armstrong, 564; Mr. Whetham, 564; Prof. Oliver J. Lodge, 564; Mr. W. J. Pope, 564; Dr. H. C. Pocklington on the Radiation of a Black Body on the Electro-magnetic Theory, 564; Mr. C. E. S. Phillips on the Apparent Emission of Kathode Rays from an Electrode at Zero Potential, 564; Mr. J. B. B. Burke on the Phosphorescent Glow in Gases, 564

*Section A* (*Department of Astronomy*).—Opening Address by Dr. A. A. Common, F.R.S., Chairman of the Department, 471; Prof. Todd on the Application of the Electric Telegraph to the furtherance of Eclipse Research, 565; Prof. Todd on Operating Eclipse Instruments Automatically, 565; Prof. Todd on the Use of a Wedge of Yellow Optical Glass in giving correctly Graduated Photographic Exposures of the Partial Phases of an Eclipse and the Corona, 565; the Rev. A. L. Cortie on the Classification of Sun Spots, 565; Prof. Turner on a Cheap Form of Micrometer for determining Star Positions on Photographic Plates, 565; Dr. W. J. Lockyer's Comparison of the Details of the Prominences and Corona on Photographs of the recent Eclipse taken by Prof. Langley in America, and Sir Norman Lockyer in Spain, 565; Mr. A. R. Hinks on the New Form of Refracting Telescope recently erected at Cambridge, 565; Mr. A. R. Hinks on Preparations for determining the Solar parallax by Observations of Eros, 565; Prof. Turner, 565; Mr. W. E. Plummer on Some Points connected with the Photography of a Moving Object, 565; Mr. A. R. Hinks, 565; Mr. John Herschel on his Method of Observing and Recording the Paths of Meteors, 565; Mr. C. T. Whitwell on the Duration of Totality of the Solar Eclipse of May 28, 1900, 566

*Section B* (*Chemistry*).—Opening Address by Prof. W. H. Perkin, F.R.S., President of the Section, 476; Report of the Committee on the Teaching of Science in Elementary Schools, 566; Dr. Letts and Mr. R. F. Blake on some Problems Connected with Atmospheric Carbonic Anhydride and on a New and Accurate Method of Determining its Amount, 566; Mr. W. Ackroyd on the Distribution of Chlorine in West Yorkshire and on the Limiting Standard of Acidity for Moorland Waters, 566; Dr. T. W. Hime on the Effects of Copper on the Human Body, 566; Prof. H. B. Dixon and Mr. F. W. Rixon on the Specific Heat of Gases up to a Temperature of 400°, 566; Mr. F. H. Neville on the Chemical Compounds contained in Alloys, 566; Prof. J. A. Ewing and Mr. W. Rosenhain on the Crystalline Structure of Metals, 567; Messrs. H. J. H. Fenton and H. O. Jones on a Simple Method of Comparing the "Affinities" of Certain Acids, 567; Mr. W. J. Pope on Recent Developments in Stereochemistry, 567; Prof. J. Bredt and Prof. Ossian Aschan on the Constitution of Camphor, 567; Report of the Committee on Isomeric Naphthalene Derivatives, 567; Report of the Committee on Isomeric Derivatives of Benzene, 567; Dr. J. B. Cohen and Mr. H. D. Dakin on the Chlorination of the Aromatic Hydrocarbons and the Constitution of the Dichlorotoluenes, 567; Mr. C. F. Cross on the Action of Caro's Reagent on Furfural, 567; Mr. T. Fairley on the Heating and Lighting Power of Coal Gas, 567; Dr. A. Liebmann on the Recent Improvement in the Textile Industries, 567; Mr. F. W. Richardson on Bradford Sewage and its Treatment, 567; Mr. W. Leach, 568; Mr. W. B. Bottomley, 568

*Section C* (*Geology*).—Opening Address by Prof. W. J. Sollas, F.R.S., President of the Section, 481; Prof. W. B. Scott on Recent Explorations in Patagonia, 587; Prof. J. Milne's Report of the Seismological Committee, 587; Mr. S. W. Cuttriss on the Pot-holes and Caves of the Mountain Limestone Districts of North-west Yorkshire, 587; the Rev. W. Lower Carter and Mr. A. R. Dwerryhouse on the Subterranean Drainage of the Limestone, 587; Mr. E. Greenly on the Ancient Peneplains in North Wales, 587; Dr. G. Abbott on the Concretionary Structures of the Magnesium Limestone of Durham, 587; Prof. W. J. Sollas, F.R.S., on a Concealed Coalfield beneath the London Basin, 587; Mr. R. H. Tiddeman on the Formation of Reef-knolls, 587; Mr. J. E. Marr, 587; Mr. W. Gibson on Rapid Changes in the Thickness and Character of the Coal-measures of North Staffordshire, 587; the Rev. J. F Blake on the Registration of Type Specimens, 587; Mr R. Kidston on Plant-life during the Growth of the Coal measures, 587; Mr. A. Strahan on the Physical Condition during the Growth of the Coal-measures, 587; Mr. J. E. Marr on the Geological Evidence of the Conditions under which Coal was Formed, 588; Dr. Horace Brown, 588; Prof. P. F. Kendall, 588; Mr. R. D. Oldham, 588; Mr. J. J. H. Teall on the Plutonic Complex of Cnoc-na-Sroine (Sutherlandshire), 588; Prof. K. Busz on a Granophyre Dyke Intrusive in Gabbro at Ardnamurchan (Scotland), 588; Prof. A. P. Coleman on the Recent Discovery of a Ferriferous Horizon in the Huronian North of Lake Superior, 588; Mr. F. W. Harmor on the Influence of Winds upon Climate during Past Epochs, 588; Dr. Monckman, Mr. E. Wilson, Mr. A. Jowett, Mr. H. B. Muff, on the Glacial Phenomena of the West Riding, 588; Mr. J. W. Stather on the Glaciation of the East Riding, 588; Mr. R. H. Tiddeman on the Raised Beach of Gower in South Wales, 588; Mr. R. D. Oldham on the Mode of Formation of the Basal Carboniferous Conglomerate of Ullswater, 588; Mr. R. D. Oldham on the Formation of New Beaches on the Shores of Thirlmere Reservoir, 588; Mr. G. W. Lamplugh on the Evidence as to the Age of the English Wealden Series, 588

*Section D* (*Zoology*).—Opening Address by Ramsay H. Traquair, F.R.S., 502; Mr. Eagle Clark on the Migration of British Birds, 588; Mr. R. C. L. Perkins on the Zoology of the Sandwich Islands, 589; Prof. W. B. Scott on the Miocene Fauna of Patagonia, 589; Dr. Gregg Wilson's Exhibit of Eggs and Embryos of *Ornithorhyncus*, 589; Major Ronald Ross on Malaria and Mosquitoes, 589; Prof. S. J. Hickson on *Dendrocometes*, 589; Dr. J. F. Gemmill on the Anatomy of the Head in Cyclopean Trout Embryos, 589; Prof. R. Burckhardt on Some Causes of

Brain-configuration in Selachians, 589; Prof. Marcus Hartog on a Peptic Zymase in Young Embryos, 589; Dr. R. Irvine on the Mechanical and Chemical Changes which take place during the Incubation of Eggs, 589; Prof. Gotch on the Physiological Effect of Local Injury in Nerve, 589; Mr. R. T. Günther on *Mnestra parasites*, 589; Prof. L. C. Miall on the Respiratory Organs of Aquatic Insects, 589; Report of the Committee on the Structure, Formation and Growth of the Coral Reefs of the Indian Ocean, Mr. Stanley Gardiner, 589–90; Prof. R. Burckhardt on the Anatomy and Systematic Position of the *Laemargidae*, 590; Mr. N. Annandale on the Appearance and Habits of Some Malay Insects, 590; Prof. E. B. Poulton's Photographs illustrating the General Principles of Müllerian Mimicry, 590; Prof. Lloyd Morgan's Experiments on the Avoidance of Distasteful Forms by Birds, 590; Messrs. F. W. Gamble and F. W. Keeble on the Colour Changes of Various Prawns, 590

*Section E* (*Geography*).—Presidential Address by Sir George Robertson, 590; Mr. E. G. Ravenstein on Foreign and Colonial Surveys, 590; Colonel Johnson, 590; Colonel Sir Thomas H. Holdich on the Question of a Railway Connection between Europe and India, 590; Mr. G. C. Chisholm on the Probable Economic Changes following the Development of the Resources of China, 590; Report of the Committee on the Climate of Tropical Africa, 590; Mr. E. G. Ravenstein on the Geographical Distributions of Relative Humidity, 590; Mr. R. T. Günther on the Coast of the Phlegræan Fields near Naples, 591; Dr. H. R. Mill on Profs. Pettersson and Nansen's New Insulating Water-bottle, 591; Dr. H. R. Mill on the Treatment of Regional Geography, 591; Mr. T. G. Rooper on the Teaching of Geography in the Elementary Schools of the West Riding, 591; Mr. E. R. Wethey's Method of Teaching Geography, 591

*Section F* (*Economic Science and Statistics*).—Opening Address by Major P. G. Craigie, 509

*Section G* (*Mechanical Science*).—President, Sir Alexander Binnie; Prof. Hele Shaw on the Question of the Resistance of Road Vehicles to Traction, 609; Mr. J. Watson on the Nidd Valley Waterworks of Bradford, 609; Mr. J. MacTaggart on the Disposal of House Refuse in Bradford, 609; Mr. E. K. Clark on the Construction of Shop Buildings in Large Engineering Works, 610; Mr. Glass on the Coal and Iron Ore Fields of Shansi and Honan, 610; Sir Wm. Preece and Mr. F. J. Behr on the Proposed Mono-Rail High-speed Electric Railway between Manchester and Liverpool, 610; Mr. A. Mallock on the Measurement of the Tractive Force, Resistance and Acceleration of Trains, 610; Mr. W. T. E. Binnie on a New Form of Self-registering Rain Gauge, 610; Mr. W. Dawson on the Demerbe System of Tramway Construction, 610; Mr. J. H. Barker and Prof. Ewing's Combined Integrating Wattmeter and Maximum Demand Indicator, 610; Prof. Goodman's New Form of Calorimeter for Measuring the Wetness of Steam, 610; Mr. A. T. Walmisley on the Use of Expanded Metal in Concrete, 610

*Section H* (*Anthropology*).—Opening Address by Prof. John Rhys, President of the Section, 513; Dr. John Beddoe on the Vagaries of the Cephalic Index, 633; Prof. Macalister, 633; Prof. A. Francis Dixon on Certain Markings on the Frontal Part of the Human Cranium and their Significance, 633; Mr. W. L. H. Duckworth on Nine Crania collected by Mr. J. Stanley Gardiner in his Expedition to Rotuma, 633; Mr. W. L. H. Duckworth on some Anthropological Observations of the Pangan Tribe of Aborigines in the Malay Peninsula, 633; Dr. David Waterson on the Developmental Changes in the Human Skeleton from the Point of View of Anthropology, 633; Prof. A. Macalister on Perforate Humeri from Ancient Egyptian Skeletons, 633; Prof. J. D. Cunningham on the Sacral Index, 633; Prof. J. D. Cunningham on the Microcephalic Brain, 633; Dr. A. C. Haddon on the Textile Patterns of the Sea-Dyaks, 634; Mr. W. Rosenhain on the Making of a Malay "Kris" and on the Malay Method of producing Chains by Casting, 634; Prof. Macalister, 634; Prof. H. Louis on the "Kingfisher" Type of a Malay "Kris," 634; Mr. H. Ling Roth on Permanent Artificial Skin Marks, 634; Mr. F. Ll Griffith on the System of Writing in Ancient Egypt, 634; Mr. Arthur J. Evans on the New Scripts Discovered by Him in Crete, 526 and 634; Dr. C. Hose and Mr. W. McDougall on the Animal Cults of the Natives of Sarawak and their Bearing on the Problems of Totemism, 634; Mr. Hartland, 635; Mr. W. G. Aston on the Japanese *Gohei* and the Ainu *inao*, 635; Mr. David Boyle on the Paganism of the Civilised Iroquois of Ontario, 635; Dr. John Beddoe on the Anthropology of West Yorkshire, 635; Mr. J. Gray on the Physical Characteristics of the Population of West Aberdeenshire, 635–6; Mr. D. Randall-MacIver on the Present State of Our Knowledge of the Modern Population of Egypt, 636; Report of the Committee for the Ethnographical Survey of Canada, 636; Report of the Committee on the Natural History and Ethnography of the Malay Peninsula, Mr. W. W. Skeat, 636; Mr. A. M. Bell on the Occurrence of Flint Implements of Palæolithic Type on an Old Land Surface in Oxfordshire, 636; Mr. J. Paxton Moir on the Stone Implements of the Natives of Tasmania, 636; Prof. E. B. Tylor, 636; Mr. H. Ling Roth, 637; Dr. A. C. Haddon on Relics of the Stone Age of Borneo, 637; Dr. C. Hose, 637; Mr. Butler Wood on the Prehistoric Antiquities of Rumbolt's Moor near Bradford, 637; Mr. Butler Wood on the Preservation of Local Antiquities, 637; Dr. A. C. Haddon, 637; Mrs. Armitage on some Yorkshire Earthworks, 637; Mr. D. G. Hogarth on the Cave of Psychró in Crete, 637; Mr. Arthur J. Evans, 637; Mr. J. L. Myres, 637

*Section K* (*Botany*).—Opening Address by Prof. S. H. Vines, F.R.S., President of the Section, 536; Mr. Kidston on the Flora of the Coal Measures, 610; Mr. Seward on the Climatic and other Physical Conditions under which Coal was Formed, 610; Dr. Horace Brown on the Possible Richness in $CO_2$ of the Atmosphere of the Coal Period, 610; Prof. Bower on the Sand-binding Plant of the Dunes on the Scotch Coast near Berwick, 611; Mr. Samuel Margerison on British Sylviculture, 611; Mr. Albert Wilson on the Great Smoke Cloud of the North of England and its Influence on Plants, 611; Prof. Marshall Ward, F.R.S., on Embryonic Tissues, 611; Mr. Henry Jackson on the Formation of Starch from Glycollic Aldehyde by Green Plants, 611; Mr. E. A. Newell Arber on the Effect of Salts on the $CO_2$ Assimilation of *Ulva latissima*, 611; Prof. Letts and Mr. J. Hawthorn on the Relation of *Ulva latissima* to the Pollution of Sea-water by Sewage, 611; Miss Elizabeth Dale on the Intumescences of *Hibiscus vitifolius*, 611; Miss Ethel Sargant on a Fourth Type of Transition from Stem to Root-structure, 611; Dr. D. H. Scott, F.R.S., on the Presence of Seed-like Organs in certain Palæozoic Lycopods, 611; Dr. D. H. Scott, F.R.S., on the Primary Structure of certain Palæozoic Stems referred to *Araucarioxylon*, 612; Prof. A. C. Seward, F.R.S., and Miss Elizabeth Dale on the Structure and Affinities of *Dipteris conjugata*, 612; Miss R. F. Shove on the Structure of the Stem of *Angiopteris evecta*, 612; Mr. A. G. Tansley on the Conducting Tissues of Bryophytes, 612; Mr. W. C. Worsdell on the Origin of Modern Cycads, 612; Prof. Overton on the Osmotic Properties and their Causes in the Living Plant and Animal Cell, 612; Mr. Harold Wager on a Demonstration of the Structure and Attachment of the Flagellum in *Euglena Viridis*, 612; Mr. Harold Wager on the Behaviour of the Nucleolus during Karyokinesis in the Root-apex of Phaseolus, 612; Miss Ethel N. Thomas on Double Fertilisation in a Dicotyledon *Caltha palustris*, 612; Mr. J. Lloyd Williams on the Germination of the Zoospore in Laminariaceæ, 613; Mr. J. Lloyd Williams on *Dictyota*, 613; Prof. Vuillemin on the *Azygospores* of *Entomophthora gloeospora*, 613; Mr. J. Parkin on Fungi found in Ceylon Growing upon Scale-insects, 613; Mr. R. H. Biffen on the Life-history of *Acrospeira mirabilis*, 613; Mr. T. W. Woodhead on the Structure of the Root-nodules of *Alnus glutinosa*, 613; Prof. F. E. Weiss on a Gymnosporangium from China, 613; Prof. Trow on the Biology and Cytology of Pythium, 613; M. Poirault and Mr. E. J. Butler's Observations on Pythium, 613; M. Poirault and Mr. E. J. Butler's Observations on Chytridineæ, 614

British Birds, C. W. Wyatt, 100

British Coal-fields, the Duration of the, E. Lozé, Bennett H. Brough, 124

British Flora, the Origin of the, Clement Reid, F.R.S., 268

British Islands, the Lepidoptera of the, Charles G. Barrett, 317

British Museum, Catalogue of the Lepidoptera Phalanæ in the, Vol. II., Catalogue of the Arctiadæ (Nolinæ, Lithosianæ), Sir George F. Hampson, Bart., 77; (Natural History) Catalogue of the Fossil Bryozoa in the Department of Geology, the Cretaceous Bryozoa, Vol. I. Dr. J. W. Gregory, 125
British People, Origin and Character of the, Nottidge Charles Macnamara, 172

Villard, 47; Temperature of Potential Gradient in Rarefied Gases, G. C. Schmidt, 92; Mechanical Motions under Influence of Kathode and Röntgen Rays, L. Graetz, 92; Energy of Kathode Rays, W. Cady, 93; the Kathode Rays, P. Villard, 191; Discontinuity of Kathodic Emission, P. Villard, 240; Production of Kathode Rays by Ultra-violet Light, P. Lenard, 335; Significance of Kathode Rays in connection with Mechanism of Discharge, Dr. Otto Berg, 628; Reflection and Mechanical Effect of Kathode Rays, 639; Sources and Properties of Becquerel Rays, Prof. G. H. Bryan, F.R.S., 151; Meeting of Röntgen Society, 179; the American Holtz Machine, 179; Dr. Rémy's Localising Apparatus, 180; the Radiation of Uranium, Henri Becquerel, 191; the Uranium Radiation, Henri Becquerel, 312; Production of X-Rays by Battery Current, J.

Trowbridge, 211; Cadett and Neall's X-Ray Paper, 253; Influence of Spark-gap on Generation of Röntgen Rays, A. Winkelmann, 568; Newton's Rings from Selenium Rays, A. C. Longden, 273; Phosphorescence Unaffected by Magnetic Field, A. de Hemptinne, 323; Artificial Radio-active Barium, A. Debierne, 383; a "Dark" Lamp, Gustave le Bon, 532; Radiation of a Black Body on the Electro-magnetic Theory, Dr. H. C. Pocklington, 564
Raffles (Sir Stamford), England in the Far East, H. E. Egerton, 548
Rails, Steel, the Cause of Fracture of, 437
Railways: The Proposed Railway up Mont Blanc, J. and H. Vallot, 62; the Metropolitan District Short Electric Railway Line, 107; the Halford Gradient Railway, 180; the Conditions of High Speed on Railways, 181; Specially built Tram for Experiment on Atmospheric Resistance, 200; the Transbaikalian Railway, 253; What Pressure is Dangerous on Electric Railways with Overhead Trolley, William Rung, 399; Railways and Moving Platforms, Prof. John Perry, F.R.S., 412; Lieut.-Colonel W. Sedgwick, 436; Electric Traction in Germany, 532; on the Question of a Railway Connection between Europe and India, Colonel Sir Thomas W. Holdich, 590
Rainfall of the Northern Counties of England, on the, J. Hopkinson, 563
Rainfall, Symons's British, H. Sowerby Wallis, 435
Ramage (H.), on a Method of Investigating Correspondence between Spectra, 563
Rambaut (Dr. A. A.), Unpublished Observations at Radcliffe Observatory, 1774–1838, 64
Randall-MacIver (D.), on the Present State of our Knowledge of the Modern Population of Egypt, 636
Range-finders, Prof. W. Stroud, 607
Ransome (W. L.), Carnotite, 432
Rats: Bacteriological Methods of Exterminating Rats, J. Danysz, 84; Rats and Plague, Dr. Frank Tidswell, 273
Ravenstein (E. G.), on Foreign and Colonial Surveys, 590; on the Geographical Distributions of Relative Humidity, 590
Ray (Sidney H.), the Peopling of Australia, 621
Rayet (G.), Comet 1900*b* (Borelly-Brooks), 464
Rayleigh (Lord, F.R.S.), the Mechanics of Flight, 108; the Weight of Hydrogen Desiccated by Liquid Air, 189; Viscosity of Gases as affected by Temperature, 287
Reorganisation of the Education Department, the, 209
Reale Accademia dei Lincei, Anniversary Meeting of, 430
Reasoning, the Psychology of, Alfred Binet, 388
Rebière (A.), Pages Choises des Savants Modernes, 6
Reclamation of Land from Tidal Waters, the, Alexander Beazeley, 266
Recognition Marks, Antelopes and their, R. I. Pocock, 584
Recording Telephones, 371
Red and Blue Pigments, Note on some, Prof. T. D. A. Cockerell, 31
Red Sea, Origin and Formation of, A. Issel, 201
Redlich (Dr. K.), Cambrian Fossils of Eastern Salt-Range (India), 36
Reed (F. R. C.), Igneous Rocks of Waterford Coast, 167
Reed (Captain Wm. J.), Tenacity of Life of the Albatross, 621
Reef-knolls, on the Formation of, R. H. Tiddeman, 587; J. E. Marr, 587
Reform of Mathematical Teaching, the, David Mair, 389; Henry Woollen, 436; W. F. Beard, 466; C. E. Stromeyer, 523; Oliver Heaviside, 548
Refracting Telescopes, Colour Screens for, T. J. J. See and G. H. Peters, 37
Refraction of the Eye, the, including a Complete Treatise on Ophthalmometry, A. Edward Davis, 6
Reid (Clement, F.R.S.), the Origin of the British Flora, 268
Relation of Stimulus to Sensation, the, Prof. C. Lloyd-Morgan, F.R.S., 278
Religion: Malay Magic: being an Introduction to the Folklore and Popular Religion of the Malay Peninsula, W. W. Skeat, 145
Rémy's (Dr.) Localising Apparatus for Röntgen Rays, 180
Repington (C.), Eggs of Wood Leopard Moth, 321
Reservoir-burst at Forres, 457
Resins: Die Harze und die Harzebehälter, A. Tschirch, 316
Resistance Coils, improved Standard, R. S. Whipple, 563

REVIEWS AND OUR BOOKSHELF:—
La Spedizione di sua Altezza Reale il Principe Luigi Amedeo di Savoia, Duca degli Abruzzi, al Monte Sant' Elia (Alaska), 1897, Dottore Filippo de Filippi, 1
Vorlesungen über Hydrodynamische Fernkräfte nach C. A. Bjerknes' Theorie, V. Bjerknes, Prof. G. H. Bryan, F.R.S., 3
Photo-micrography, Dr. Edmund J. Spitta, 4
Notes on Sport and Travel, George Henry Kingsley, 5
Irrigation and Drainage, Principles and Practice of: their Cultural Phases, F. H. King, 5
The Refraction of the Eye, including a Complete Treatise on Ophthalmometry. A Clinical Text-book for Students and Practitioners, A. Edward Davis, 6
A Key to the Birds of Australia and Tasmania, with their Geographical Distribution in Australia, R. Hall, 6
Pages Choisies des Savants Modernes, A. Rebière, 6
Les Vieux Arbres de La Normandie, Henri Gadeau de Kerville, 7
Pompeii: its Life and Art, August Mau, 7
Naturalism and Agnosticism, James Ward, 25
The Races of Europe: a Sociological Study, William Z. Ripley, Prof. A. C. Haddon, F.R.S., 27
Histologische Beiträge, Heft VI.: Ueber Reauktionstheilung, Spindelbildung, Centrosomen und Cilienbildner im Pflanzenreich, E. Strasburger, Prof. J. B. Farmer, 28
Mechanism of Weaving, T. W. Fox, 29
Leçons d'Optiques Géométrique à l'Usage des Éléves de Mathématiques Spéciales, E. Wallon, 30
Therapeutic Electricity and Practical Muscle Testing, W. S. Hedley, 30
Lessons in Botany, Prof. George F. Atkinson, 30
Outlines of Plant Life, with Special Reference to Form and Function, Prof. Charles Reid Barnes, 30
The Grammar of Science, Karl Pearson, F.R.S., 49
The Principles of Mechanics Presented in a New Form, Heinrich Hertz, 50
The Reports of the Magicians and Astrologers of Nineveh and Babylon, R. C. Thompson, 51
Éléments de la Théorie des Nombres, E. Cahen, 52
Atlas of Urinary Sediments, with Special Reference to their Clinical Significance, Dr. Herman Riedel, 53
Dante, Edmund G. Gardner, 53
The Farmstead, Prof. J. P. Roberts, 53
Object Lessons in Botany from Forest, Field, Wayside and Garden, Edward Snelgrove, 53
The Principles of Bacteriology, Dr. Ferdinand Hueppe, Dr. A. C. Houston, 73
Vinification dans les Pays Chauds—Algérie et Tunisie, J. Dugast, 74
A Vertebrate Fauna of the Shetland Islands, A. H. Evans, T. E. Buckley, 75
Introduction to Physical Chemistry, James Walker, Prof. Arthur Smithells, 76
Catalogue of the Lepidoptera Phalaenæ in the British Museum, Vol. II. Catalogue of the Arctiadæ (*Nolinae*, *Lithosianae*) in the Collection of the British Museum, Sir George F. Hampson, Bart., 77
Giordano Bruno, zur Erinnerung an den 17 Februar, 1600, Alois Reihl, 77
Christian Friedrich Schönbein, 1799–1868, George W. A. Kahlbaum und Ed. Schaer, Prof. R. Meldola, F.R.S., 97
Scientific Papers, Peter Guthrie Tait, Sec. R.S.E., Prof. Horace Lamb, F.R.S., 99
British Birds, with some Notes in Reference to their Plumage, C. W. Wyatt, 100
Our Native (American) Birds, how to Protect them and Attract them to our Homes, D. Lange, 100
Der Ursprung der Kultur, L. Frobenius, 101
The Amateur's Practical Garden Book, C. E. Hunn, L. H. Bailey, 101
Man and His Ancestor: a Study in Evolution, Charles Morris, 101
A First Geometry Book, J. G. Hamilton, F. Kettle, 101
The Theory of Electrolytic Dissociation, H. C. Jones, 121
Traité de Zoologie Concrète. T. ii. 1$^{\text{re}}$ Partie. Mésozoaires—Spongiaires, Yves Delage, Edgard Hérouard, 122
Les Charbons Britanniques et leur Épuisement, E. Lozé, Bennett H. Brough, 124

Ueber den Bau und die Entwicklung der Linse, Dr. Carl Rabl, 125
Building Construction for Beginners, J. W. Riley, 125
Catalogue of the Fossil Bryozoa in the Department of Geology, British Museum (Natural History). The Cretaceous Bryozoa. Vol. i. Dr. J. W. Gregory, 125
Malay Magic: being an Introduction to the Folklore and Popular Religion of the Malay Peninsula, W. W. Skeat, 145
The Norwegian North Polar Expedition, 1893–96, Fridtjof Nansen, J. F. Pompeckj, A. G. Nathorst and R. Collett, 146
The Cyanide Process of Gold Extraction, James Park, 148
The Cause and Prevention of Decay in Teeth, J. Sim Wallace, Dr. Harold Austen, 149
Erinnerungen aus meinem Leben, A. Kolliker, 169
Theory of Differential Equations, A. R. Forsyth, F.R.S., 170
Origin and Character of the British People, Nottidge Charles Macnamara, 172
The Geography of the Region about Devil's Lake and the Dalles of the Wisconsin, Prof. R. D. Salisbury, W. W. Atwood, 172
Monistische Gottes- und Weltanschauung, J. Sack, 172
First Stage Hygiene, Robert A. Lyster, 173
Among the Birds in Northern Shires, Charles Dixon, 177
A Monograph of Christmas Island (Indian Ocean), Physical Features and Geology, C. W. Andrews, 193
Metallurgy of Lead and Silver. Part II. Silver. Henry F. Collins, 194
The History of Language, Henry Sweet, 195
Micro-organisms and Fermentation, Alfred Jörgensen, 195
Photography in Colours, R. C. Bayley, 195
Leçons Nouvelles sur les Applications Geometriques du Calcul Différentiel, W. de Fannenberg, 196
Elementary Illustrations of the Differential and Integral Calculus, Augustus De Morgan, 196
Allgemeine Biologie, Prof. Dr. Max Kassowitz, Prof. H. Marshall Ward, F.R.S., 217
Introduction to English, French and German Phonetics, Laura Soames, 220
Psychologie der Naturvölker, Dr. J. Shultze, 220
The Study of Bird-life, W. P. Pycraft, 221
An Introduction to the Differential and Integral Calculus and Differential Equations, F. G. Taylor, 221
Monographie der Turbellarien II. Tricladida Terricola (Landplanarien), Prof. Ludwig von Graff, F. W. Gamble, 241
Papers on Mechanical and Physical Subjects, Osborne Reynolds, F.R.S., 243
Sette Anni di Caccia Grossa é Note di Viaggio in America, Asia, Africa, Europa, Count Felice Scheibler, 244

Sea, the Total Eclipse Observed at, Colonel E. E. Markwick, 183
Sea Coast Destruction and Littoral Drift, W. H. Wheeler, 400
Sea-dredging, Building-land made by, 158
Sea-Dayaks, on the Textile Patterns of the, Dr. A. C. Haddon, 634
Seals of Kerguelen Island, the Elephant, R. Hall, 628
Sedgwick (Lieut.-Colonel W.), Railways and Moving Platforms, 436
See (T. J. J.), Colour Screens for Refracting Telescopes, 37
Seed-like Organs in certain Palæozoic Lycopods, on the Presence of, Dr. D. H. Scott, F.R.S., 611
Seeley (Prof. H. G., F.R.S.), an Anomodont Reptile from Bunter Sandstone of Reichen, 94; Theriodont Reptile from Baviaans River, Cape Colony, 262
Seismology: Elastic Constants of Rocks and Velocity of Seismic Waves, Dr. H. Nagaoka, 36; Action of Horizontal and Vertical Pendulums, Dr. G. Agamennone, 62; Greek Earthquakes, 1893–8, M. Eginitis, 85; Bolletino della Societá Italiana Sismologica, 93, 286; the Colaba (Bombay) Observatory, 181; the Great Earthquake of June 12, 1897, R. D. Oldham, 305; Earthquakes of 1897 in Philippines, P. J. Coronas, 555; Report of the Seismological Committee of the British Association, 562; Prof. J. Milne's Report of the Seismological Committee of the British Association, 587
Self-instruction in the Practice and Theory of Navigation, the Earl of Dunraven, 337
Sell (W. J.), Aminochloropyridines, 143
Sella (A.), Evaporation not Productive of Loss of Electricity, 458
Sellon (R. P.), Standardisation of Electrical Engineering Plant, 135

Semmola (Prof. E.), Variations with Altitude of Air Potential, 375

Senderens (J. B.), Addition of Hydrogen to Acetylene in the Presence of Copper, 168; Addition of Hydrogen to Acetylene in Presence of Reduced Iron and Cobalt, 191; Addition of Hydrogen to Acetylene and Ethylene in Presence of Finely-divided Platinum, 264; Action of Reduced Nickel on Acetylene, 312; Action of Finely-divided Metals on Acetylene and Ethylene, 336; Addition of Hydrogen to Ethylene in Presence of Reduced Metals, 240

Senior (Edgar), a Handbook of Photography in Colours, 434

Sensation, the Relation of Stimulus to, Prof. C. Lloyd Morgan, F.R.S., 278

Serotherapy: a Possible Preventive of African Horse-sickness, Dr. G. C. Purvis, 83; Standardisation of Anti-venomous Serum, W. Myers, 215

Seurat (L. G.), Morphology of Respiratory Apparatus of Larva of *Bruchus ornatus*, 639

Severn Bore, the, Vaughan Cornish, 126

Sewage: the Bacterial Treatment of Sewage, Dr. Frank Clowes and Dr. Houston, 128; on Bradford Sewage and its Treatment, F. W. Richardson, 567; W. Leach, 568; W. B. Bottomley, 568; on the Relation of *Ulva latissima* to the Pollution of Sea-water by Sewage, Prof. Letts, J. Hawthorn, 611

Seward (Mr.), on the Climatic and other Physical Conditions under which Coal was formed, 610

Seward (Prof. A. C., F.R.S.), on the Structure and Affinities of *Dipteris conjugata*, 612

Sharpe (Dr. Benjamin F.), a New Instrument to Measure and Record Sounds, 80

Shaw (P. E.), Electric Micrometer, 67

Shaw (W. N., F.R.S.), the Daily Weather Report of the Meteorological Office, 300

Shenstone (W. A., F.R.S.), Working Silica in the Oxy-gas Blowpipe Flame, 20

Sherrington (Prof. C. S., F.R.S.), Experimentation on Emotion, 328

Shetland Isles, a Vertebrate Fauna of the, A. H. Evans and T. E. Buckley, 75

Shimizu (S.), a String Alternator, 286

Ship-building, the Use of Steel in, B. Martell, 90

Ships, the Steadying of, Prof. G. H. Bryan, F.R.S., 186

Shooting in Schools, Percussion Caps for, Sir Lauder Brunton, F.R.S., 54

Shove (Miss R. F.), on the Structure of the Stem of *Angiopteris evecta*, 612

Shufeldt (Dr. R. W.), Psychology of Fishes, 63

Siam, Surveying and Exploring in, James McCarthy, 571

*Siboga*, the Cruise and Deep-sea Exploration of the, in the Indian Archipelago, 327

Siderostat and Cœlostat, Orientation of the Field of View of the, A. Fowler, 428

Sidgwick (Prof. Henry), Death of, 456; Obituary Notice of, 496

Silica in the Oxy-gas Blowpipe Flame, W. A. Shenstone, F.R.S., and H. G. Lacell, 20

Silk, Spider, Manufacture in Madagascar, M. Nogue, 17

Silver, Metallurgy of Lead and, Henry F. Collins, 194

Simmons (A. T.), Elementary Physics and Chemistry, 620

Simmonds (C.), Huxley and his Work, 495

Simon (L. J.), New Pyrogenous Product from Tartaric Acid, 616; Isopyrotritaric Acid, 639

Skeat (W. W.), Malay Magic: being an Introduction to the Folklore and Popular Religion of the Malay Peninsula, 145; Report of the Committee of the British Association on the Natural History and Ethnography of the Malay Peninsula, 636

Skeleton, Human, on the Developmental Changes in the, from the Point of View of Anthropology, Dr. David Waterson, 633

Skeletons, Ancient Egyptian, on Perforate Humeri from, Prof. A. Macalister, 633

Skin Marks, on Permanent Artificial, H. Ling Roth, 634

Sladen (Walter Percy), Death of, 179; Obituary Notice of, 256

Smith (Dr. C. A.), the Clays of Alabama, 274

Smith (G. F. Herbert), Method for Determining Refractive Indices of Minerals of Low Symmetry, 239

Smith (H. G.), Amyl Ester of Eudesmic Acid in Eucalyptus Oils, 384

Smith (R. G.), Double Staining of Spores and Bacilli, 640

Smith (William G.), Recent Investigations on Rust of Wheat, 352

Smithells (Prof. Arthur), Introduction to Physical Chemistry, James Walker, 76

Smithsonian Expedition, the Total Solar Eclipse as observed by the, 246

Smyth (the late Prof. Piazzi), some Notes on his Work in Spectroscopy, Prof. A. S. Herschel, F.R.S., 161

Smoke Cloud of the North of England and its Influence on Plants, the Great, Albert Wilson, 611

"Snake-stone," *Plotosus canius* and the, D. Hervey, 79

Snake-stone, the, E. H. L. Schwartz, 302

Snake-venom, Captain R. H. Elliot, 180; Standardisation of Anti-venomous Serum, W. Myers, 215; the South Indian Snake-men, Captain R. H. Elliott, 324

Snape (H. L.), Racemic and Optically Active Forms of Isoamarine, 143

Snelgrove (Edward), Object Lessons in Botany from Forest, Field, Wayside, and Garden, 53

Snow-drifts on Ingleborough in July, Prof. T. Mckenny Hughes, F.R.S., 389; Prof. T. G. Bonney, F.R.S., 412

Snyder (V.), Invariant Scrolls In Collineations which leave a Group of Five Points Invariant, 381

Soames (Laura), Introduction to English, French, and German Phonetics, with Reading Lessons and Exercises, 220

Sociology: the Races of Europe, a Sociological Study, William Z. Ripley, Prof. A. C. Haddon, F.R.S., 27

Solander (Dr. Daniel), Illustrations of the Botany of Captain Cook's Voyage Round the World in H.M.S. *Endeavour*, in 1768–71, 547

Solar Parallax, Determination of, 377

Solar Radiation, Report of the British Association Committee on Solar Radiation on Experiments conducted by Prof. Callendar on the Modified Copper-cube Actinometer, 562

Solidification of Alloys, the, Fred. T. Trouton, F.R.S., 523

Sollas (Prof. W. J., F.R.S.), Opening Address in Section C of the British Association, 481; on a Concealed Coal Field Beneath the London Basin, 587

Solution Theory Applied to Molten Iron and Steel, John Parry, 128

Sound Waves, the Photography of, Prof. R. W. Wood, 342

Sounds, a New Instrument to Measure and Record Sounds, Dr. Benjamin F. Sharpe, 80

Sources and Properties of Becquerel Rays, Prof. G. H. Bryan, F.R.S., 151

South African Philosophical Society, 216, 264, 464

Space, Pseudospherical, Dynamics of, Prof. D. de Francesco, 18

Species, the Subordination of the Individual to the Welfare of the, 593

Spectrum Analysis, Comparison of Stellar with Laboratory Spectra, Sir Norman Lockyer, 23; Spectrum of β Lyræ and η Aquilæ, O. Belopolsky, 70; Temperature Control of Spectrograph, Prof. W. W. Campbell, 137; some Notes on the late Prof. Piazzi Smyth's Work in Spectroscopy, Prof. A. S. Herschel, F.R.S., 161; the Band Spectrum of Aluminium, G. A. Hemsalech, 335; Spectrum of Radium, Eug. Demarçay, 336; Spectrum of Radium, C. Runge, 568; Influence of Slight Impurities on Argon and Helium Spectra, P. Lewis, 381; Fluorescence and Phosphoresence in Electric Discharge through Nitrogen, P. Lewis, 381; the New Spectrographs for the Potsdam Great Refractor, Prof. C. H. Vogel, 459; Dr. S. P. Langley's Chart of the Infra Red Spectrum from 0·7 to 5·3 μ obtained by the Bolometric Method, 562; H. Ramage, on a Method of Investigating Correspondence between Spectra, 563; Spectra of Hydrogen and Aqueous Vapour, J. Trowbridge, 568; Spectroscopic Examination of Colour Produced by Simultaneous Contrast, G. J. Burch, 615

Spencer (Herbert), Genesis of the Vertebrate Column, 620

Speyers (C. L.), Boiling Point Curves, 92

Spider-silk Manufacture in Madagascar, M. Nogue, 17

Spitta (Dr. Edmund J.), Photo-micrography, 4

Sport and Travel, Notes on, George Henry Kingsley, 5

Sporting Tour, Count Scheibler's, 244

Stability of a Swarm of Meteorites and of a Planet and Satellite, the, Prof. A. Gray, F.R.S., 582

Staffordshire, North, on Rapid Changes in the Thickness and Character of the Coal Measures of, W. Gibson, 587

Standards for Faint Stellar Magnitudes, 398

Stanley (Hiram M.), an Outline Sketch, Psychology for Beginners, 245

## MOUNT ST. ELIAS.

*La spedizione di sua Altezza Reale il Principe Luigi Amedeo di Savoia, Duca degli Abruzzi al Monte Sant' Elia (Alaska)* 1897. Da Dottore Filippo de Filippi; illustrata da Vittorio Sella. Pp. xvii + 273; with 34 plates, 4 panoramic views, 2 maps and 115 figures in text. A beneficio delle Guide Alpine Italiane. (Milano: U. Hoepli, 1900.)

MOUNT ST. ELIAS, with an altitude, as now ascertained, of 18,092 feet, stands—a majestic cornerpost—exactly at the angle where the Alaskan boundary-line ceases to run parallel to the coast and strikes northward along the 141st meridian, and its summit is now generally acknowledged to lie on the Canadian side of the frontier. Whether it maintain its supposed pre-eminence among the mountains of the North American continent, or whether it eventually prove to be overtopped by Mount Logan, its great neighbour on the north, or, as the most recent explorations seem to indicate, by Mount McKinley, one of the yet unvisited peaks to the westward, it must, from its commanding position on the verge of the open ocean, always impress the imagination as the grandest of the Alaskan Chain. In recalling the fact that the mountain was for long erroneously supposed to be a volcano, Mr. Douglas Freshfield has told us, on the authority of the poet himself, that Tennyson had Mount St. Elias in mind when he described the landscape of a volcano among snow as one of the pictures on the walls of "The Palace of Art" (see *The Alpine Journal*, vol. xix. p. 174).

So far as our present knowledge goes, nowhere else on the face of the globe is there so great a vertical range of snow and ice as among these Alaskan mountains. On Mount St. Elias the permanent snow-line comes down to within about 3000 feet of the sea, while the enormous glaciers nourished by the excessive humidity of the climate not only descend to sea-level, but unite and spread out in a vast plain of ice covering an estimated area of 1500 square miles between the foot of the mountain and the ocean.

Thus entrenched in ice sheets, so that even its base is defended, it is not surprising that the mountain withstood several attacks before it was conquered. The first attempt was made, in 1886, by Messrs. Libbey, Schwatka and Seton-Karr; the next, in 1888, by Messrs. Topham, Broke and Williams; the third and fourth, by Prof. I. C. Russell, in 1890 and 1891; and the fifth, by Prof. H. G. Bryant, in 1897, almost simultaneously with the successful Italian expedition. Of these explorers, Prof. Russell achieved in every way the most important results, bad weather alone preventing his complete success in 1891, after an altitude of 14,500 feet had been attained and the practicability of the ascent had been demonstrated. Prof. Russell correctly determined the height of the mountain, and carried out investigations upon its physical characteristics which proved of high scientific importance. Lieut. Seton-Karr had previously called attention to the singular condition of the glaciers at the foot of the mountain, where immense piles of morainic debris, in places overgrown with dense vegetation, hide the marginal surface of the ice; but it was not until Prof. Russell published his more adequate descriptions that geologists fully recognised the value of the phenomena of the "piedmont" ice in elucidating the conditions of ice-covered lowlands in general during the Glacial Period, and especially during its closing stages. So closely has Prof. Russell's name become associated with the mountain, that one cannot stifle a regret that the satisfaction of being first upon the summit did not fall to his lot. In the volume before us, however, we are glad to find a graceful acknowledgment of the work of previous explorers, in a chapter having for its motto this quotation, from Mr. D. Freshfield:—

> "Those who went first and opened the way are not less entitled to credit than those who came afterwards and reaped the fruit of their predecessors' labours."

The leader of the Italian expedition, H.R.H. Prince Louis of Savoy, in planning an ascent higher than the Alps could offer, had at first contemplated an attack upon one of the great peaks of the Himalayas. Forced by unfavourable circumstances to abandon this idea, he turned for consolation to Mount St. Elias. He could not have selected a more princely amusement, or a better exercise in skilful organisation and patient endurance. That he achieved his object without mishap, and that he and his little band of fellow-countrymen had the patriotic satisfaction of planting the Italian flag on a summit assuredly never before trodden by the foot of man, was due to the careful forethought with which all the preliminary arrangements of the expedition were planned.

A graphic account of the ascent was communicated by one of the party, Dr. Filippo de Filippi, to the English Alpine Club a few months afterwards, and was published in the *Alpine Journal* for May 1898. As chronicler of the expedition, Dr. Filippi has now expanded his story in the handsome and portly volume before us, in which he deals at full length with the conditions of the climb, and describes in glowing language the wild grandeur of the scenery. The beautiful photogravure plates and the illustrations in the letterpress, with which the book is so bountifully provided, are reproduced from photographs taken, for the most part, by Vittorio Sella, who was also of the party, and these are especially valuable as a faithful and permanent record of the physical characters of this seldom-visited region, and particularly of the untraversed wilderness of snow and mountain peaks to the northward of St. Elias. Among many that are excellent, there is one plate (p. 136), showing the snowy eastern spurs of St. Elias delicately fluted by innumerable avalanches, which seems to us peculiarly impressive.

Of the ten chapters of the book, only five deal with the actual ascent; the first three, and also the final chapter, are devoted to the outward and homeward journeys; the fourth to the previous history of the mountain; and appendices, covering seventy-four pages, to the equipment and scientific results of the expedition.

As Russell had foretold, the mountaineering difficulties encountered during the climb were slight, and the adventure resolved itself into a long, arduous struggle upward for thirty days, usually in wretched weather, over interminable snow-fields and glaciers. The character of the climb was pithily given by one of the guides, in answer to inquiries after his return:—"C'est comme le Breithorn, seulement beaucoup plus haut." The expedition, consisting of the Prince with four compatriots, five Italian guides, and ten Americans who acted as porters, landed safely near Point Manby, at the foot of the moraine of the Malaspina ice-field, on the evening of June 23, and on July 1 started forward across the ice, all subsequent encampments being upon snow. Traversing the Malaspina in three days, partly in dense fog, the party struck upward along the eastern flank of its great tributary the Seward Glacier, which was afterwards crossed, and the Agassiz Glacier gained, at an altitude of only 3480 feet, by Russell's previous route through the Dome Pass, on July 13. Thence the explorers forced their way slowly up the Newton Glacier, through labyrinths of crevasses and ice-falls, for thirteen days, of which only three were fine. Fortunately the fog and snow which fell to their lot were unaccompanied by either wind or electrical disturbance; nor did the party suffer from cold, the temperature ranging steadily between 25° and 35° F. Their progress along this glacier averaged only about 1 mile 500 yards daily. At this stage they received news that the expedition led by Prof. Bryant, which had set out a few days ahead of them, had been compelled to return to the coast owing to the illness of one of its members, after having reached the foot of the Newton Glacier.

The Italians were greatly impressed with the vivid colouring of the névé and ice even in the thickest weather, the tints ranging from brilliant turquoise and azure to the deepest blue, without the greenish tinge familiar to them in the Alps. This and the weird atmospheric effects in these mountain solitudes are eloquently described by Dr. Filippi.

Having left the American porters behind, and established their advance camp on the col at the head of the Newton valley, at an altitude of 12,287 feet, the success of the mountaineers depended solely upon the weather. Fortunately this proved more favourable than at the lower elevations, and they were able, without delay, to attack the summit. It was absolutely calm and clear on July 31, when after a heavy climb of 5800 feet from their last bivouac, during which the majority of the party were more or less affected by mountain-sickness, the Prince and his comrades reached the crest just before noon. The thermometer registered a temperature of 10·5° F., and the barometer stood at 15 inches 15 lines. The height of the mountain as determined by the barometer was 18,092 feet, which is in remarkably close agreement with Russell's figures, 18,100 feet, obtained by triangulation.

From the summit they saw the majestic mass of Mount Logan to the north-eastward, sinking north-westward into a very intricate lower chain, while to the westward was a chaos of low ridges, névés and glaciers, overtopped at a distance of some hundred miles or so by three great snowy giants as yet unexplored, which proffer substantial work for the future.

Then came the descent and the return to the coast, which was safely reached in ten days. Some of the lower ridges overlooking the Malaspina Glacier, where they had previously found snow, were now knee-deep in blossoming plants.

The appendices to the volume are, from a scientific standpoint, not particularly important. The first describes the equipment of the expedition in detail, and should be of service to explorers of similar regions. The excellent plan was adopted of packing the supplies in tin boxes, each containing sufficient material of every kind for twenty-four hours. The second appendix consists of meteorological tables, giving the simultaneous observations made daily between June 25 and August 3 by the expedition, and by the Rev. C. J. Hendricksen, of the Swedish Mission at Yakutat, at the foot of the mountain. The third deals with the health of the party. The absence of colds, rheumatism, or other ill results from the trying conditions of the journey is made the subject of comment; and the symptoms which effected most of the explorers during the final stages of the ascent are fully discussed, but it is thought that these might be in part attributed to excitement and want of sleep. The only case of real illness was that of one of the American porters, who, after having passed a night, during the return, on ground covered by vegetation, on the Hitchcock Hills, was seized with an attack of malaria while crossing the Malaspina Glacier. The terrible plague of mosquitoes on the coastal strip of forest is especially mentioned. Another appendix, on the zoological material, is principally devoted to the description of a new arachnid and of a new oligochæte annelid collected on the snow. An appendix on the rocks and minerals is for the most part a discussion of Russell's previous work, but contains the information that the outcrops near the summit of the mountain consist of typical diorite passing locally into hornblendite.

The ascent of Mount St. Elias was an achievement worthy of a prince, and this handsome volume is worthy of the achievement. Beautifully printed, magnificently illustrated and tastefully bound, it reflects credit upon all concerned in its production. But (alas! the inevitable but!) it has no index. G. W. L.

## A HYDRODYNAMICAL THEORY OF ACTION AT A DISTANCE.

*Vorlesungen über hydrodynamische Fernkräfte nach C. A. Bjerknes' Theorie.* Von V. Bjerknes. Band i. Pp. 338; with 40 figures. (Leipzig: Johann Ambrosius Barth, 1900.)

THEORIES of matter—or should we not rather call them theories of *force*, since, in "explaining" the properties of matter, we are mainly concerned with those manifestations which we say are due to "force"—naturally fall into two distinct classes. The first class includes those hypotheses which regard continuous matter as being built up of discrete particles, and the direct action of finite portions of matter as being due to action at a distance of these particles. The second class includes those hypotheses which regard these particles as singularities in a continuous medium, and which attribute their action at a distance to the direct agency of the medium. In a certain sense, these two theories are reciprocal. In both, certain attributes are localised at points, and it is necessary to bridge over the distance between these points. According to the first hypothesis, a field of force pervades the intervening gaps; according to the second, they are filled with a distribution of mass. The belief that both hypotheses are possible, enables us to imagine that there may be no limit to the smallness of the scale on which Nature conducts her operations, the phenomena occurring in any region being made to depend in their turn on others occurring in the far more minute regions which are regarded as constituting its ultimate elements, and these elements being in turn capable of further subdivision, and so on indefinitely.

In 1852, Lejeune-Dirichlet, being unacquainted with the works of Green and Stokes on this subject, published a paper containing the solution of the problem of the motion of a sphere in an incompressible fluid. In a course of lectures given at Göttingen in 1855–56, Dirichlet gave the corresponding solution for a sphere fixed in a steady current, and invited his pupils to attempt the solution for an ellipsoid. Among these pupils were Schering, who solved the problem, and C. A. Bjerknes, who gave a generalisation for space of $n$ dimensions. At this time the doctrine of action at a distance may have been said to be at its zenith, and Göttingen had given birth only a few years previously to the last brilliant product of that doctrine, Weber's Law. As a foreigner, Bjerknes was, however, less influenced by the views then prevailing in the Göttingen school, and a volume of Euler's correspondence falling into his hands caused him to oppose the doctrine of action at a distance. A fresh light was thrown on the hypothesis of a continuous all-pervading medium by Dirichlet's discovery that a sphere moving in an incompressible perfect fluid experiences no retardation from the fluid, and an impetus was given to Bjerknes to develop Dirichlet's investigations in a direction widely differing from anything then contemplated by his professor.

From the effects of purely translational motions of two spheres, Bjerknes was led on to consider the mutual actions of two pulsating spheres, and discovered that such spheres attract or repel one another according as their phases are the same or opposite, the law of force being that of the inverse square. Bjerknes found, moreover, that the expressions for the forces acting on a sphere moving in liquid consisted of two terms, which he distinguished as "inductional forces" and "energy forces," a result which he arrived at by considering the expressions for the pressures on the spheres, but which might have been found more readily had Thomson and Tait's application of Hamilton's principle been then known to him. About 1875, Bjerknes published a paper in which he established the hydrodynamical law of action and reaction, and the analogy with electric and magnetic action at a distance; and in the following year he gave an independent investigation based on the Hamiltonian principle.

From 1875 onwards, Bjerknes appears to have occupied himself chiefly with the terms of lowest order in the expressions for the forces; and in 1878 he discovered the law of rotation for oscillating spheres. Since then he seems to have devoted his attention mainly to electric and magnetic analogies, and in the middle of his eightieth year he completed the discussion of the "inductional forces," and by this means pushed the analogy between hydrodynamic action at a distance and electromagnetic phenomena as far as it could be pushed without departing from the fundamental hypotheses.

A complete account of these investigations was never published, and it remained for his son, Prof. V. Bjerknes, to embody them in the present volume. For three years Prof. V. Bjerknes has delivered courses of lectures on the subject at the University of Stockholm, and the book is practically based on these lectures. It is divided into four parts: the first, an introductory part, dealing with the general principles of vector fields and hydrodynamical equations; the second, dealing with the motion of the liquid surrounding a system of moving spheres treated from a kinematical standpoint; the third, dealing with the influence of the pressures on the motion of the spheres themselves; and the fourth, with the theory of apparent actions at a distance, of hydrodynamical origin. In the second part, the diagrams of the stream lines due to a moving, oscillating or pulsating sphere in various fields of force are noticeable for their elegance.

It is to be wished that the courses of lectures which Prof. V. Bjerknes delivered on the work of his father could be taken as models of what university lectures should be, for the development of a theory such as the present affords an excellent and not difficult insight into the methods of mathematical analysis. So long as our English university colleges are, to a great extent, in the hands of oligarchies, who attach more importance to such trifles as the handwriting and spelling of matriculation or medical preliminary students than to higher scientific study, such courses of training will only be accessible to those who seek them in countries more enlightened in the matter of scientific education than Great Britain. We can readily imagine that Bjerknes' theories may find their way into many transatlantic universities among the "classics of science." They have, indeed, no small claim to be regarded as classical. It is true, as Prof. V. Bjerknes points out, that his father's and Kirchhoff's work in several cases somewhat overlapped, but it would appear that in developing the theory of motion of spheres in liquids as a basis for explaining the properties of matter, Bjerknes stood entirely on ground of his own making. Other theories involving the conception of a continuous medium have sprung up; we have had the vortex-atom theory before us, and we now find it necessary to postulate the existence of an ether, whose attributes resemble those of an elastic solid rather than a fluid. At the present time few will regard the hypothesis of pulsating spheres as of more than classical interest. As having been first developed in the face of a prevalent belief in the doctrine of action at a distance, and as ingenious methods of replacing this action at a distance by the action of an intervening medium, the application of the term "classical" to these investigations of C. A. Bjerknes may not be altogether without justification.

## PHOTO-MICROGRAPHY.

*Photo-micrography.* By Dr. Edmund J. Spitta. Pp. xi + 163. (London: The Scientific Press, Ltd., 1899.)

A QUARTER of a century has now elapsed since the renaissance of the art and science of photo-micrography. Up to that time much of the best work in this direction was accomplished in America by Lieut.-Colonel Woodward, of Washington, whose successful photographs of diatoms excited the admiration of all microscopists who saw in his productions the faithful delineations of those "markings" on them, on which many hours of microscopical manipulation had been spent in bringing their delicate tracery to a correct definition. From that time to the present the fascination of transferring the minutest details of histological and biological science to the photographic plate has found many ardent votaries, with the result of improved apparatus and lenses corrected to such a degree of accuracy for this work that sharp and well-defined images can now be obtained in a manner that would have been a boon and a revelation to workers twenty-five years ago.

Amongst the latest exponents of this branch of microscopical science we must name that of the author of the book under consideration.

Dr. Spitta in this work on photo-micrography has dealt with the subject very fully and from a scientific standpoint, so that the student who takes up this branch of the photographic art is thoroughly furnished with all the information necessary to the accomplishment of perfect work, leaving, however, only that amount of *personal experience* to be obtained and which will be demanded of every one who first embarks on this art, and without which he is liable to be landed in many difficulties.

In Chapter i. the author deals with illuminants, a by no means unimportant point for consideration; for although we have several good illuminants for low power work, it is when we come to work with the highest power objectives that either the lime-light or that of the electric arc lamp must be employed to produce the best possible results. These lights are not always readily accessible; but as the aspiring student most probably will try his 'prentice hand on low power work, the single wick lamp burning the best paraffin oil will furnish him with a light sufficiently rich in actinic rays that, provided the proper length of exposure be given, will result in a very successful negative. Dr. Spitta in Chapter ii. proceeds to give directions for obtaining photo-micrographs by low power objectives, dealing with this in such a lucid manner that the student who closely follows his clear description cannot fail in being rewarded by satisfactory results, being assisted in his work by algebraical formulæ and illustrations of simple but effective apparatus.

Chapter iii. deals with medium power photo-micrography, and contains some very necessary cautions relative to the avoidance of vibrations in the apparatus, for, as the author observes, "when photographing at 1000 diameters, 1/1000 of an inch shake in the specimen makes a shift of one inch in the photographic plate," or he might have said in the photographic *image;* therefore the absolute necessity of the most perfect stability, not only in the apparatus but even in the studio, can be readily understood and provided for—even a heavy tread on the floor of an adjoining room being sufficient to disturb the steadiness of the optical arrangement. Dr. Spitta describes different methods whereby this difficulty may be overcome. Allowance must also be made for the expansion of the metal of the microscope from the heat of the illuminant, for even in low power work, say of 250 diameters, the heat from the oil lamp must not be considered a negligible quantity, and must be considered so far that no photographic exposure should be attempted till the metal has had time to become fully expanded.

Chapter iv. is overloaded with woodcuts of different makes of microscopes valuable as affording the student a choice of various instruments, but by no means necessary to his work, as any one of these is sufficient for attaining good medium power work. This chapter also deals with the subject of lenses and eyepieces and the accessory fittings of the microscope generally; but there is one point that must have the greatest attention, and that is the fine adjustment, and Dr. Spitta does well in laying great stress upon its importance; nothing is more embarrassing to the operator, when perhaps everything else in the apparatus is working well, to find that the fine adjustment by which he hopes to obtain that sharp definition without which his work is valueless, is altogether useless from faulty construction, and Dr. Spitta describes the various forms of this all-important addition to the photo-micrographic installation.

The remaining three chapters of this work treat of such subjects as substage fittings, coloured screens, and the various subsidiary apparatus useful in high power or "critical" photo-micrography. These particulars do not bear the condensation that is necessitated by the space allotted to this report, but are full of information for the guidance of the photo-micrographic student and will materially assist him in his work. A valuable feature is included in the appendices, and is headed "25 common faults in photo-micrography; their causes and means of cure"; by a reference to p. 152 every error that may present itself in the beginner's work is described, the reason for it given, and the remedy indicated. Added at the end of the book are five plates of representative work in photo-micrography, the work of the author, while a copious index brings the work to a conclusion.

## *GEORGE KINGSLEY'S LIFE AND WRITINGS.*

*Notes on Sport and Travel.* By George Henry Kingsley. With a memoir by his daughter, Mary H. Kingsley. Pp. viii + 544. (London: Macmillan and Co., Ltd., 1900.)

THIS is a book, we venture to think, that most readers will lay down with deep regret—regret that a very talented writer, an acute observer, and an ardent sportsman (in the best sense of the word) should have bequeathed so little of his experiences to the world. For George Kingsley, a member of a clever family (or, as his biographer will have it, a member of a clever generation of an ancient family), was evidently a man far above the ordinary intellectual level, and enjoyed unrivalled opportunities of adding to our store of knowledge by travel in distant lands at a time when they were still, to a great extent, populated by their native denizens and unspoiled by the march of civilisation. Unfortunately, however, he seems to have been devoid of those regular and methodical habits of work by which alone the results of a life of exploration and travel can be properly recorded, and we have consequently to be content with mere scraps and fragments of a vast store of information.

From such scraps and fragments as the editor, who is to a great extent also the author, of the present volume has been able to save from oblivion, we glean how keen an observer and how true a lover of nature was Dr. Kingsley. Whether among the coral-girt isles of the South Pacific, when they were yet in great part free from the "beachcomber," or on the prairies of the "wild west," at a time when the bison were still to be numbered by hundreds, if not by thousands, his descriptions of scenery and animals are life-like pictures.

The greater part of the account of the author's travels is given in the memoir by his daughter, which occupies more than a third of the whole volume, and is, in great measure, in the form of letters or of extracts from the same. And here we take the opportunity of expressing our sense of the excellent manner in which Miss Kingsley—herself a traveller and writer of world-wide repute—has discharged what must evidently have been a task of no ordinary difficulty.

Kingsley (in company with the late Lord Pembroke) visited the South Seas in the late "sixties"—a time when yachting in those latitudes had not come into vogue; and such descriptions as he has left of the natives and natural products only make us regret that they were not fuller. Fish seem especially to have attracted his attention; but when he states that he disbelieves the story of a *Chaetodon*[1] shooting water at a fly, the editor should have added that the only fish which performs this feat is a species of *Toxotes*, whose southern range only extends to North Australia, so that it could not have come under the ken of the author.

The travels in Canada and the United States were undertaken in company with Lord Dunraven, between 1870 and 1875; parts of them being described by the latter in "The Great Divide."

Of the various collected papers of Dr. Kingsley, perhaps the most interesting to the naturalist is the one entitled "Among the Sharks and Whales." Here the author graphically describes, as an eye-witness, certain encounters between the larger Cetaceans and smaller members of the same order, together, perhaps, with other denizens of the deep. We are told, for instance, how some of these creatures, of thirty feet or so in length, were seen to leap clean out of the water, and then to fall with a sounding "smack" that could be heard half a mile off. But whether the creatures in question were attacking a whale, or leaping for mere fun, the author was unable to determine. Neither could he say definitely whether or no they were "killers." And he seems, indeed, to be somewhat confused between "killers" and "threshers"; although, as to the sharks commonly called by the latter name, he denies that they ever attack whales, adding that he has never even known a shark of any kind throw itself out of the water.

R. L.

## *OUR BOOK SHELF.*

*Irrigation and Drainage, Principles and Practice of, their Cultural Phases.* By F. H. King, Professor of Agricultural Physics in the University of Wisconsin, author of "The Soil." The Rural Science Series. Pp. xxi + 502. (New York: The Macmillan Company London: Macmillan and Co., Ltd., 1899.)

THE object of this book, as stated in its preface, is "to present, in a broad yet specific way, the fundamental principles which underlie the methods of culture by irrigation and drainage," and we may say that we consider the author successfully does this.

The introductory chapter treats of the importance of water in cultivation, and in it a number of interesting experiments on the amount of water absorbed by cereals and other plants, and the weight of dry matter produced are described, from which it appears that with cereals the amount of water used varies from about 300 to 500 lbs. per pound of dry matter produced. The general result of these experiments is considered to show "that well-drained lands in Wisconsin, and in other countries having similar climatic conditions, are not supplied naturally with as much water during the growing season as most crops are capable of utilising, and hence that all methods of tillage which are wasteful of soil moisture detract by so much from the yield per acre."

---

[1] The editor avows a difficulty in deciphering some of the MS. which came into her hands, and therefore suggests the possibility of a certain amount of mis-spelling. Some naturalist friend would, however, doubtless have corrected the following errors, viz.:—P. 61, *Chetadons* for *Chaetodons*; p. 222, *Haroldus* for *Harelda*; p. 414, *Megaptera australis* for *Balaena australis*; p. 421, *Ovules* and *Mutras* for *Olives* and *Mitras*; and p. 424, *Orcus* for *Orca*.

Similar experiments have been made with other crops, as, for instance, potatoes, and the importance of such experiments is, as stated further on in the book, "because only such knowledge as this can show how economical or how wasteful our methods of tillage may be, and how nearly we are realising the largest profits which are possible to the business."

The conditions of rainfall under which irrigation is practised in different parts of the world are discussed, and the means of "conserving the moisture of the subsoil" by proper tillage pointed out. An excellent account is given of the depth of root penetration in the soil, which is illustrated, as is the rest of the book, by some very good and instructive engravings. A short account is given of sewage irrigation; and the idea that the milk of cows fed on sewage produce is in any way detrimental is disposed of by quotations from Sir Henry Littlejohn, and from Mr. Spier, the Scottish Dairy Commissioner. Methods of diverting streams for irrigation are carefully described and fully illustrated, as also are the methods of applying the water to the ground. In Part ii. (a small portion at the end of the book) the necessity for soil drainage is insisted on, and the methods of carrying it out are described.

The book altogether is very readable, although the spelling of some of the words seems curious to an English reader. It is also well printed, and the only misprint noticed is on p. 403, where the word "denitrification" is used instead of "nitrification." W. H. C.

*The Refraction of the Eye, including a Complete Treatise on Ophthalmometry. A Clinical Text-book for Students and Practitioners.* By A. Edward Davis, A.M., M.D. Pp. 431. (New York: The Macmillan Co., 1900.)

THIS volume should prove a valuable addition to the library of the ophthalmic surgeon, for though several books on retinoscopy have been published, this is the only work on ophthalmometry yet written in English.

It comprises a description of Javal and Schiötz's modification of Helmholtz's ophthalmometer, together with full instructions in the use of the instrument; the necessity of forming a clear mental picture of the state of the eye from the results of an experiment being rightly insisted upon.

One hundred and fifty illustrative cases are included in the text, and a comprehensive index has been appended, so that the student can readily find a parallel to any case which may give him trouble. One hundred and nineteen diagrams, including a clear and well-drawn woodcut of the ophthalmometer of Javal and Schiötz, are distributed throughout the text.

Although the advantages which may be gained by the use of the ophthalmometer are insisted upon, the author has taken great pains to indicate the limitations of its usefulness. By its aid we may determine with accuracy the radii of curvature of the cornea in various meridians; but the author endorses the generally accepted opinion that there is no definite relation between the curvature of the cornea and the refractive condition of the eye, as far as hypermetropia or myopia are concerned. Myopia usually depends upon an elongation, and hypermetropia upon a shortening of the axis of vision. Strangely enough, in cases of extreme myopia, a somewhat flattened cornea is generally met with. Nevertheless, in cases of simple hypermetropia and myopia, the ophthalmometer eliminates the question of corneal astigmatism. The routine of examination followed by the author is (1) use the ophthalmometer; (2) use trial lenses and test cards; (3) use the ophthalmoscope; (4) if after two tests on different days the result is still unsatisfactory, employ a mydriatic and use the retinoscope in addition to the other tests. It is stated that (1) to (3) suffice for 99 per cent. of uncomplicated cases.

In the use of test glasses, it is recommended that a series of positive lenses, gradually increasing in power, should first be employed. By this means spasmodic accommodation is avoided. The fact that the use of atropine can so often be dispensed with is of great importance, since many men might hesitate to have their eyes examined if this necessitated a temporary cessation of their business duties.

A number of instructive cases are included, showing the serious results which may follow on the prescription of unsuitable glasses for a patient. Not only severe pain and inability to use the eyes for any length of time, but even personal disfigurement may be produced. Thus a case is recorded (p. 307) of a patient whose eyes were being forced into a divergent squint by the use of prismatic glasses. After a careful examination, the prisms were discarded and suitable lenses were ordered, with the result that, after two weeks, complete comfort and the possibility of working with satisfaction were enjoyed for the first time for many years.

Altogether this book gives us a good idea of the vast advantages to the human race which have resulted from the optical researches of Helmholtz, culminating in the invention of the ophthalmometer and the ophthalmoscope. E. E.

*A Key to the Birds of Australia and Tasmania, with their Geographical Distribution in Australia.* By R. Hall. Pp. xii + 116; plate and map. (Melbourne: Mullen and Slade; London: Dulau and Co., 1899.)

WERE it nothing more than a synopsis of Australian birds, with just sufficient in the way of description to enable the different species to be easily recognised, this well-printed little "Key" would be to a great extent of merely local interest. But since the author has very wisely made geographical distribution its leading feature, the work appeals to a much wider circle of students than would otherwise have been the case.

In his Report on the Zoology of the Horn Expedition, Prof. Baldwin Spencer recently divided Australia into three zoological sub-regions; namely, (1) the Torresian, embracing the northern and eastern districts as far as South Queensland; (2) the Barsian, comprising eastern New South Wales, Victoria and Tasmania; and (3) the Eyrean, including the remainder of the mainland. These sub-regions are further split up into "areas," and the fact that bird-distribution accords with such a parcelling-out of the continent from other lines of evidence affords important testimony in support of Prof. Spencer's views. It is noteworthy that the South Queensland area forms the headquarters of the Australian Passeres, a fact for which there must surely be some adequate physical reason, if only it could be discovered. The total number of species recorded is 767, among which the black emu is believed to be extinct; and, so far as we have been able to verify them, the diagnoses of the various groups and species seem well adapted to their purpose. The work appears singularly free from errors and misprints, and ought to be in the hands of every Australian bird-lover. R. L.

*Pages Choisies des Savants Modernes.* By A. Rebière. Pp. viii + 620. (Paris: Nony et Cie, 1900.)

THIS is a series of extracts (translated into French when not written in that language) from the works of eminent men of science. It appeals mainly to the general reader, and the best that can be hoped of it is that it may induce some members of this class to study the works of one or other man of science seriously. A scientific writer does not appear to the best advantage in "tit-bits" selected from his works; and, except as a possible stimulus, the value of such a miscellany as this cannot be reckoned very high. The portraits, of which there is a considerable number, will probably be found, by scientific readers, the most interesting feature of M. Rebière's compilation.

*Les Vieux Arbres de La Normandie.* By Henri Gadeau de Kerville. Fasc. iv. Pp. 219 + 352. (Paris: J. B. Baillière et fils, 1899.)

THIS instalment of M. de Kerville's careful monograph contains twenty views of trees from photographs by the author, accompanied by detailed descriptions and historical notes. The work is well and conscientiously done, whilst the illustrations are well selected and admirably reproduced in collotype. The trees here shown include ten oaks, six yews, two beeches, a lime and a poplar. As the photographs of the deciduous trees have been taken in very early spring, before the opening of the buds, their ramification and general architecture are shown to the greatest advantage. With this volume, *à propos* of a notable oak-tree growing at Isigny-le-Buat, the author includes an interesting account of recorded cases of mistletoe upon oaks in Normandy. He is able to produce evidence in support of some twenty-seven recorded instances. The book will appeal to all tree-lovers; may it stimulate some to similar studies. We remember to have seen something of the kind for Northumberland nearly thirty years ago in the *Transactions* of the Tyneside Naturalists' Field Club.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### The Nature of the Solar Corona.

I SEE in the recenty-published number of *Science Abstracts*, No. 802, that there is every reason to think that the corona line is not represented by any dark line in the solar spectrum. I write to call attention to the way this confirms the suggestion that the corona is an aurora round the sun. In the March number of the *Annalen der Physik* for this year, p. 462, Herr Cantor describes experiments from which he concludes that there is no absorption corresponding to the emission of light by a gas which is caused to radiate by an electric discharge. He makes certain deductions as to the temperature of the gas which emphasise the difficulty of defining "temperature" in the case of a non-steady state; but, whatever is to be deduced from his observation, it certainly lends weight to the suggestion that the corona is due to an emission of a similar character to that of a gas transmitting an electric discharge.

April 30. GEO. FRAS. FITZGERALD.

### Rock-structures in the Isle of Man and in South Tyrol.

MR. LAMPLUGH'S recent paper referred to in his letter in NATURE of April 26 (p. 612) is devoted to an elucidation of the "relations of the Carboniferous limestone to the Carboniferous volcanic rocks" in the Isle of Man (*Q.J.G.S.* 1900, p. 11). From Mr. Lamplugh's description, these relations are very similar to the relations which I described as subsisting between the Mid-Triassic dolomitic limestone ("Mendola Dolomite") and the tufaceous "Wengen" beds of Enneberg. The "Buchenstein Agglomerate" of Enneberg, which I mentioned in my letter (NATURE, March 22), had been described in geological literature as a "Middle Triassic agglomerate" of local occurrence above "Mendola Dolomite," in the neighbourhood of eruptive outbursts of that age. My map and sections showed that the agglomerate had a limited occurrence in fault-zones and overthrust-planes where differential movement had taken place between the harder, more resisting "Mendola Dolomite" and the yielding, mixed "Wengen" series "comprising dust-tuffs and lavas, as well as fossiliferous shales and shaly limestones." I therefore explained the so-called "Triassic" agglomerate as a subsequent structure, of the nature of a shear-breccia, produced by the earth-movements of the later Alpine upheaval (*Q.J.G.S.* 1899, pp. 567, 584, Figs. 1, 4, 9, 10).

Mr. Lamplugh describes in the Carboniferous series of the Isle of Man rock-structures of brecciated limestone, tuffs with contained strips of limestone, and coarse agglomerate which had previously been referred to the effects of Carboniferous eruptive action. Mr. Lamplugh's explanation is that the various complexities in the structure of these rocks "have not been caused by the volcanic outburst, but have been brought about at a later date by the differential movement of segments of the eruptive rocks upon their original floor of limestone" (*Q.J.G.S.* pp. 15, 19, Figs. 3, 4). The parallelism between the two cases is self-evident. In 1894, I had explained on precisely the same principle of subsequent differential movement, the occurrence of certain anomalous phenomena at the *upper* limit of the Wengen-Cassian series in Enneberg, *i.e.* the limit of this plastic and compressible series against the higher horizon of Triassic calcareo-dolomitic rock, termed "Schlern Dolomite" ("Coral in the Dolomites," *Geol. Mag.* 1894, p. 55).

The parallelism in the general sequence of events in the Isle of Man and in South Tyrol is as follows:—

| *Isle of Man.* | *Enneberg.* |
|---|---|
| Pre-Carboniferous Movement. | Pre-Triassic Movement. |
| Lower Carboniferous Deposition. | Triassic Deposition. |
| Subsequent Movement. | Subsequent Movement. |

The crust-movement immediately antecedent to Triassic deposition in South Tyrol was that which accomplished the upheaval of the Permian Alps, post-Triassic crust-movement culminated in the upheaval of the present Alps (aut. *Q.J.G.S.* 1899, p. 628, and NATURE, Sept. 7, 1899, pp. 445–6).

The farther issues of my paper in showing how differential movements twist the rocks by taking place in cross-directions were not touched in my letter of March 22, for the reason that Mr. Lamplugh did not in his paper enter into the torsional results of differential movements. But, as I have elsewhere expressed, rock-torsion or "warping" goes on all the time in crust-folding, and clearly, where from any cause whatsoever there is the greatest complexity in the differential movements, there will be the greatest complexity in the torsional phenomena.

MARIA M. OGILVIE GORDON.

## POMPEII AND ITS REMAINS.[1]

THE city of Pompeii is one which will ever maintain a hold upon the imagination of cultured man, as much for what it represented in the history of civilisation, as for being the victim of one of the most awful visitations of the powers of nature which have ever befallen the abiding place of a great society of men. It is not the place here to descant upon the wealth and luxury of its inhabitants, on the bright and reckless lives which they led, on the splendour of its buildings, or even the fancied security wherein men and women lulled themselves, notwithstanding the violent shock of earthquake which shook the city to its very foundations on February 5, A.D. 63, for all these things are the commonplaces of history; but we are concerned with the remains left by the awful catastrophe which took place on August 24,

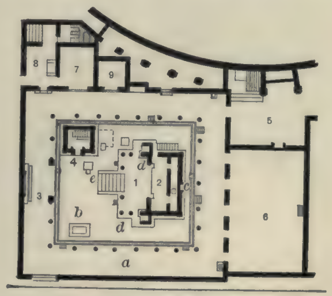

FIG. 1.—Plan of the Temple of Isis.

1, Portico; 2, cella; 3, shrine of Harpocrates; 4, purgatorium; 5, hall of initiation; 6, hall of mysteries; 7, 8, 9, abodes of priests; *a*, colonnade; *b*, refuse pit; *c*, niche for statue of Bacchus; *d d*, niches; *e*, large altar.

---

[1] "Pompeii, its Life and Art." By August Mau. Translated by F. W Kelsey. Pp. xxii + 509. (New York: The Macmillan Co., 1899.)

A.D. 79, and buried the cities of Herculaneum and Pompeii in a layer of mingled mud, lava, pumice stone, dust and wet ashes. In less than thirty-six hours Vesuvius had completely blotted out these towns and had covered the ground around for miles with pumice stones, barely as large as walnuts, to the depth of ten feet. Of the twenty thousand people who are estimated to have been in Pompeii when destruction came upon the doomed country, about two thousand perished, the rest saved themselves by flight; but fortunately for the people of our own time they were compelled to leave behind them most of the things which describe to the student and antiquary the manner of their lives, and reveal the high standard in luxury and artistic civilisation to which they had attained. The blow fell so suddenly, and the overwhelming of the city was so swiftly and effectively performed, that men and animals had no time to die in the usual manner, and the ashes which caked round them have preserved forms and scenes which, though belonging to the dead and dying, are replete with unerring suggestions of life.

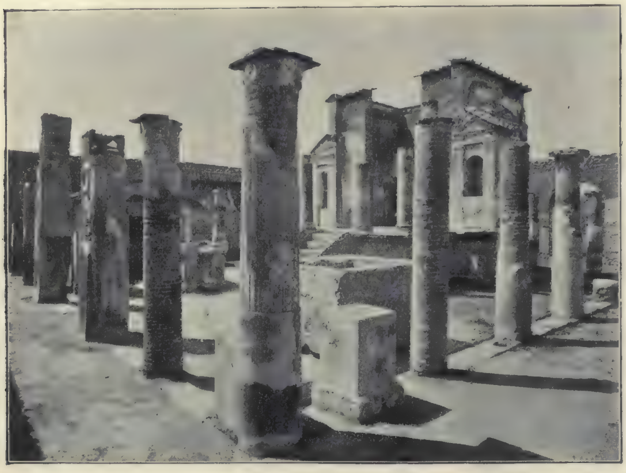

FIG. 2.—View of the Temple of Isis.

Soon after the city of Pompeii was buried, the survivors came back and began to dig out the objects of value belonging either to themselves or their friends which they knew to be in the houses. As the upper parts of many of the houses still stood above the pumice stone and ashes, they were able to locate them in many instances with convenient accuracy, and as a result there remained in Pompeii, when the searchers had finished work, but few houses which had not been partly or wholly explored. Anything like a systematic search, however, was never made, and the excavators worked most in the places which seemed to promise the best results. Among others, the builders' labourers made themselves very busy, for the costly stones and marble used in the construction of porticos, vestibules and baths, not to mention the pillars, were eagerly sought after for the building of new villas and houses. When such human vultures had battened on the remains of the town, they left what they could not, or would not, carry away to decay and desolation. For fifteen hundred years, Pompeii and its dead slept in peace, and certain pious folk comforted themselves with the view that its inhabitants, like those of the Cities of the Plain, richly deserved their punishment. About A.D. 1600, D. Fontana, who was occupied in bringing water from the Sarno to Torre Annunziata, cut a conduit through a part of the site of Pompeii, and two inscriptions were found in the course of the work. In 1719, Count Elbeuf's workmen sank a shaft on the site of Herculaneum, and reached a level corresponding with the stage of the theatre. In 1754, a number of tombs at Pompeii were discovered by the road-makers who were working to the south of the city, but no systematic attempt to leave what had been excavated uncovered and visible to all was made until 1763, when the discovery of the inscription of Suedius Clemens definitely proved that the site was that of Pompeii. A year later, the theatres, the Street of Tombs, and the villa of Diomedes were uncovered, and general interest in the work was at last awakened. Between 1806 and 1815, under Joseph Napoleon and Murat, the Herculaneum Gate and Forum were excavated; and between 1825 and 1848, a large number of beautiful houses were cleared out and made accessible to the curious and the learned. Up to this period, the work of excavation, though carried on with skill and zeal, was exceedingly unscientific; indeed, judged by the canons of the excavator of to-day, it would be pronounced to possess no system at all. In 1860, however, explorations and

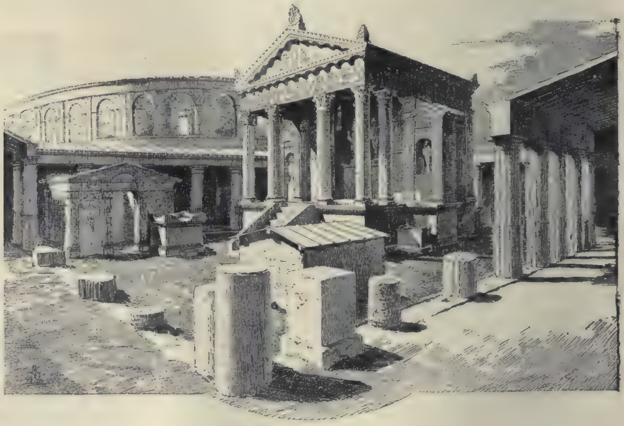

FIG. 3.—The Temple of Isis restored.

excavations on the site of Pompeii were entrusted to the hands of G. Fiorelli, and most of the excellent results which have attended the excavations made during the last forty years are due to the plan inaugurated by him. At the present time, about one-half of the site of Pompeii has been excavated, and, according to the calculations which he made as far back as 1872, the work of clearing the undisturbed parts in the western half of the ancient city, and the whole of the eastern half, will not be completed much before the year 2000. The above facts will enable the reader to grasp the magnitude of the undertaking, and to appreciate the help which is forthcoming from Prof. Mau's exhaustive work, of which we must now speak briefly.

It is well known that Prof. Mau has for more than a score of years devoted all his winters to the study of the antiquities of Pompeii, and there is little doubt that he is *facile princeps* among the experts in this special branch of Roman archæology. His articles and papers in the scientific periodicals have secured for him a high position among savants, even in his own country, and his "Mittheilungen" are at once the product of good scholarship and enthusiasm. The volume before us is not a mere translation of one previously issued, but is to all intents and purposes a new work, now published for the first time in English. Mr. Kelsey, who is responsible for the English work bearing Prof. Mau's name, is more than the translator, for he has abridged the German manuscript which he had to work from in many places, and a number of additions to the text are due to him. He has done his part of the work faithfully, and the English visitor to Pompeii has now available in his own tongue a volume in which lucidity of treatment goes hand in hand with erudition and scholarship. The English text is accompanied by twelve plates, six plans, and two hundred and sixty-three cuts, which are inserted as near as possible to the subject-matter illustrated by them. We have only one fault to find with the book—it is a little heavy to carry about. Thus having said our worst, we proceed to describe very briefly its contents. The six first chapters really form the introduction, which they are actually called, and they treat of the early history and general situation of Pompeii, the overwhelming of the city, and the excavations undertaken during the last hundred and fifty years. The last chapter of the section on building materials and architectural periods is particularly instructive, and will be read by more than the tourist. Part i. contains twenty-five chapters, which deal exhaustively with the public buildings and places of Pompeii, including the Forum, the Basilica, the Comitium, the theatres, the temples of Jupiter, Apollo, Zeus Milichius, and, strangest of all, the temple of the Egyptian goddess Isis. It will be remembered that the Ptolemies, by the help of Manetho, an Egyptian priest, and of Timotheus, a man who had peculiarly perfect knowledge of the Eleusinian Mysteries, associated certain Egyptian religious ceremonies with those of the Mysteries, in the hope of binding his Greek and Egyptian slaves together in the bonds of a common form of worship. The new cult, though it was abominated by the philosophers, was very popular, and it spread from Alexandria by way of the Delta into Syria, and from the same centre to Rome. As a result, we find that a college of priests of Isis, or Pastophori, was founded at Rome in the time of Sulla, about B.C. 80. The Romans objected to the introduction of the Egyptian gods, and three times in the space of eleven years was their temple destroyed. Oddly enough, a temple in honour of Osiris and Isis was built in Rome about B.C. 44, and before the end of the century their festival was recognised by the public calendar. But other cities of Italy were more tolerant than Rome, for a temple in honour of Serapis was standing at Puteoli B.C. 105, and not long after this date the temple to Isis was built at Pompeii. In the earthquake which took place A.D. 63 this temple suffered greatly, but it was rebuilt by Numerius Popidius Celsinus at his own expense "from the foundation." From the view given by Prof. Mau on p. 166, we see enough to show us that although the building bore slight resemblance to an Egyptian temple, there was, notwithstanding, a wish on the part of the architect to produce an unwonted effect on the mind of the beholder. The deities Osiris, Isis, Anubis and Harpocrates were represented by statues, and as they have never been found, it is probable they were carried off by the faithful on that awful day in August, A.D. 79. We know little of the ceremonies connected with the initiation into the Mysteries, but two skulls, a marble hand, two small boxes, a gold cup, a small glass vessel, and a statuette of the god nearly one inch in height seem to have played a prominent part in them. We have not space to follow Prof. Mau through his description of all the various parts of this interesting temple, but we may note that the existence of the hieroglyphic sepulchral inscription, set up for the scribe Hat on a pillar to the right of the altar, indicates the adoption in Pompeii of a widespread Egyptian custom. The

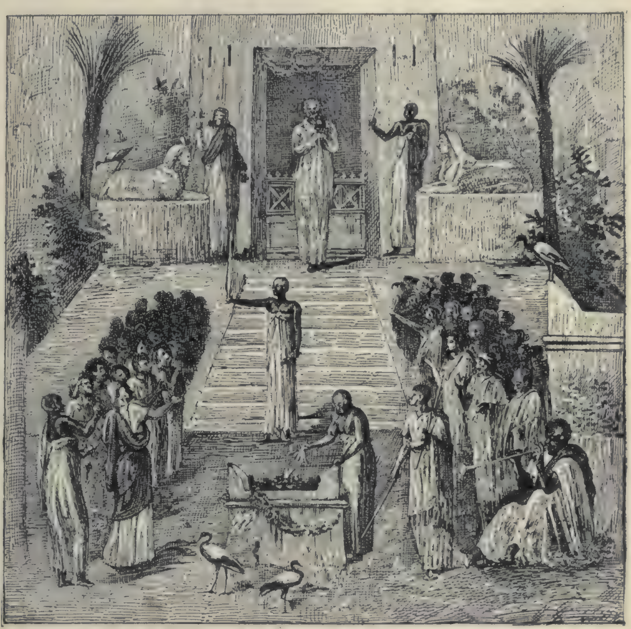

Fig. 4.—The adoration of the holy water of the Nile during the worship of Isis.

worship of Isis attracted large numbers to her temple, and the principal services took place before daybreak. The curtains were drawn aside and the statue of the goddess was presented to her worshippers, who straightway prayed to her; an hour after sunrise a hymn was sung to the rising sun, typified by Harpocrates, and the service was over. The second service of the day was held two hours after noon, and it seems to have consisted in the adoration of water in a vessel which was supposed to have been taken from the Nile. Whatever the details may have been, the services certainly had reference to scenes connected with the finding of the dead body of Osiris by his wife Isis, and they were intended to urge the beholder to renounce the present life and to prepare for a second birth into a purified and beatified state of existence in a new world. The temple of Isis at Pompeii is a remarkable relic of the adoption of a remarkable religion by the Romans, and we hope that Prof. Mau will add any new facts which he may glean from subsequent researches to the future editions of his work. The second part of Prof. Mau's volume deals with the houses of Pompeii, and it seems to us to be the best in the book, for it recalls the scenes and occurrences in the daily household life of the Pompeians in a most realistic fashion. The mind's eye has so many facts supplied to it with such lucid explanations that a street of houses appears before it without fatigue, and as the result of but little effort. Parts iii.–vi. deal with trades and occupations, the tombs, Pompeian art and inscriptions; the chapters of these sections are written in the same easy style, but at the same time the reader feels that he is being led along an interesting path by the hand of a master of his craft.

## *THE UNVEILING OF THE HUXLEY MEMORIAL STATUE.*

THE statue, by Mr. Onslow Ford, R.A., of the late Right Hon. Thomas Henry Huxley, now placed in the first right-hand recess of the Great Hall of the Natural History Museum, was unveiled by H.R.H. the Prince of Wales on Saturday last, April 28, the ceremony being performed, by his Royal Highness's desire, immediately after the meeting of the Trustees appointed for that day.

Seating accommodation had been provided for the Huxley family, the Trustees of the British Museum, the members of the Memorial Committee, and other distinguished guests and chief subscribers to the Memorial Fund, in front of the statue; and a still greater number of persons, most of whom were subscribers also, assembled in the corridors overlooking the Great Hall, and on the staircases.

There were from 700 to 800 persons present, adequately representative of all branches of science, art, law, music, and politics, and of several foreign nations. The following is a classified list of the persons more directly concerned in the ceremony:—

### *Trustees of the British Museum.*

H.R.H. the Prince of Wales.
Earl of Elgin, K.G.
Earl of Hopetoun.
Viscount Cross.
The Bishop of Winchester.
The Lord Walsingham.
The Right Hon. Sir George Trevelyan, Bart.
The Right Hon. John Morley, M.P.
Sir Nathaniel Lindley, Master of the Rolls.
Dr. W. S. Church, President of the Royal College of Physicians.
The Rev. F. H. Annesley.
Mr. Cavendish-Bentinck.
The Duke of Devonshire, K.G.
Lord Russell of Killowen.
Lord Avebury.
Viscount Peel.
Viscount Dillon.
Sir John Evans, K.C.B.
Sir Richard Webster.

### *Executive Committee of the Memorial Fund and others.*

Lord Shand (Chairman).
Sir Joseph Fayrer, Bart., K.C.S.I., F.R.S.
Sir Henry Thompson, Bart.
Sir Joseph Hooker, G.C.S.I., C.B., F.R.S.
Sir John Donnelly, K.C.B.
Sir Norman Lockyer, K.C.B., F.R.S.
Sir Michael Foster, K.C.B., M.P., F.R.S.
Sir Spencer Walpole, K.C.B.
Sir A. Geikie, F.R.S.
Mr. Briton Riviere, R.A.
Dr. P. L. Sclater, F.R.S.
Prof. G. B. Howes, F.R.S. (Hon. Secretary).
Mrs. Huxley and members of the Huxley family, to the number of thirty-two.
Sir E. Maunde Thompson and Officers of the British Museum, Bloomsbury.
Prof. E. Ray Lankester, the Director, and the Officers of the British Museum (Natural History).

Among other persons who were seated in the central enclosure were the following:—

Sir F. Abel, Bart., F.R.S.
Prof. T. Clifford Allbutt, M.D., F.R.S.
Sir L. Alma-Tadema, R.A.
Sir Edwin Arnold, K.C.I.E., C.S.I.
The Attorney-General.
Mr. Alfred Austin.
Sir Squire Bancroft.
Hon. Edmund Barton, Q.C.
Prof. Bastian, F.R.S.
Sir Lowthian Bell, Bart., F.R.S.
Mr. Horace Brown, F.R.S.
Sir T. Lauder Brunton, M.D., F.R.S.
Rt. Hon. L. Courtney, M.P.
Sir Wm. Crookes, K.C.B., F.R.S.
Mr. Francis Darwin, F.R.S.
The Earl of Ducie, F.R.S.
Sir W. Thiselton-Dyer, K.C.M.G., F.R.S.
Mr. R. Etheridge, F.R.S.
Prof. J. B. Farmer, M.A.
Lady Flower.
Prof. Le Neve Foster, F.R.S.
Dr. R. Garnett, C.B.
Dr. J. H. Gladstone, F.R.S.
Lieut.-Col. Godwin-Austen, F.R.S.
Dr. A. Günther, F.R.S.
Mr. G. Henschel.
Lord Hobhouse, K.C.S.I., C.I.E.
Prof. Victor Horsley, F.R.S.
Prof. J. W. Judd, C.B., F.R.S.
Right Hon. W. E. H. Lecky, M.P.
Sir Hugh Low, G.C.M.G.
Dr. P. Manson.
Dr. Ludwig Mond, F.R.S.
Prof. R. Meldola, F.R.S.
Sir Francis Mowatt, K.C.B.
Sir Andrew Noble, K.C.B., F.R.S.
Admiral Sir Erasmus Ommanney, Bart., C.B., F.R.S.
Prof. J. Perry, F.R.S.
Sir W. C. Roberts-Austen, K.C.B., F.R.S.
Sir Henry Roscoe, F.R.S.
Prof. A. W. Rücker, F.R.S.
Sir J. S. Burdon-Sanderson, Bart., F.R.S.
Dr. D. H. Scott, F.R.S.
Sir G. G. Stokes, Bart., F.R.S.
Prof. G. Johnstone Stoney, F.R.S.
Mr. J. J. H. Teall, F.R.S.
Prof. T. E. Thorpe, F.R.S.
Prof. W. A. Tilden, F.R.S.
Rev. Canon Tristram, F.R.S.
Sir William Turner, F.R.S.
Prof. W. F. R. Weldon, F.R.S.

Foreign nationalities were represented by:—

Dr. F. P. Moreno (of the Argentine Republic).
Major Dr. von Wissmann Germany).
Mons. L. Geoffray (France).
Mons. F. Fuchs (Congo Free State).
Prof. Batalha Reis (Portugal).
Prof. G. Paladino (of Naples).
Prof. G. Gilson (of Louvain).
Señor Don Pedro Jovar y Tovar (Spain).
Count Bottaro Costa (Italy).
Plenipotentiaries at the International Conference for the preservation of wild animals in Africa.

Punctually at the time appointed (1.15 p.m.), his Royal Highness took up a position to the spectators' left of the statue, supported by the Standing Committee of the Trustees of the Museum, with Sir Maunde Thompson and Prof. Ray Lankester; while Sir Joseph Hooker, similarly supported by the members of the Executive of the Memorial Committee, stood on the right; the sculptor, Mr. Onslow Ford, being in proximity to the statue.

The proceedings were opened by Prof. Ray Lankester, with the following introductory statement:—

YOUR ROYAL HIGHNESS, MY LORDS, LADIES AND GENTLEMEN,—The duty of briefly explaining the nature of the present proceedings has devolved upon me. I feel it to be a great privilege to discharge this duty on the occasion designed to do honour to my venerated master, Prof. Huxley. This celebration would have been no less dear to Huxley's fellow-worker and friend, the late director of this museum, Sir William Flower, who unhappily is no longer with us to witness the completion of the memorial statue which he, especially, desired to see placed in this hall.

A few months after Prof. Huxley's death in 1895, a committee was formed for the purpose of establishing a memorial of the great naturalist and teacher. At a meeting of that committee, held on November 27, 1895, at which 250 members were present, and at which his Grace the Duke of Devonshire presided, the following resolution was carried:—

> "That the memorial do take the form of a statue, to be placed in the Museum of Natural History, and a medal in connection with the Royal College of Science; and that the surplus be devoted to the furtherance of biological science in some manner to be hereafter determined by the committee, dependent upon the amount collected."

From all parts of the world, besides our own country, from every State of Europe, from India and the remotest Colonies, and from the United States of America, subscriptions have been received for the Huxley memorial, amounting in all to more than 3380*l*.

Three years ago the committee commissioned and obtained the execution of a medal bearing the portrait of Huxley, and has established its presentation as a distinguished reward in the Royal College of Science. The re-publication of the complete series of Huxley's scientific memoirs, which was proposed as one of the memorials to be carried out by the committee, has been undertaken by Messrs. Macmillan, without assistance from the committee. I am glad to be able to state that two large volumes of these richly illustrated contributions to science have been already published.

Whilst these other memorials were in progress under the auspices of the executive committee, they secured the services of Mr. Onslow Ford, R.A., to execute the statue which it had been decided by the general committee to regard as the chief object of the subscriptions entrusted to them. On the completion of the statue, the trustees of the British Museum agreed to receive it and to place it in the great hall where we are now assembled.

On behalf of the vast body of subscribers to the memorial, Sir Joseph Hooker, Huxley's oldest and closest friend, himself the survivor of that distinguished group of naturalists, including Charles Lyell, Richard Owen and Charles Darwin, who shed so much lustre on English science in the Victorian age, will hand over the statue of Huxley to the trustees of the British Museum. Your Royal Highness has been graciously pleased, as one of the trustees, to represent them on the present occasion, and to receive the statue on their behalf. The memorial statue of Huxley is the expression of the admiration, not only of the English people, but of the whole civilised world, for one who as discoverer, teacher, writer and man, must be reckoned among the greatest figures in the records of our age.

Sir Joseph Hooker then stepped forward from among the committee, and presented the statue in the following words:—

MAY IT PLEASE YOUR ROYAL HIGHNESS,—I have the honour of being deputed, by the subscribers to the statue of my friend the late Prof. Huxley, to offer it to your Royal Highness, on behalf of the trustees of the British Museum, with the intent that it should be retained in this noble hall as a companion to the statues of Prof. Huxley's distinguished predecessors, Sir Joseph Banks, Mr. Darwin and Sir Richard Owen. It would be a work of supererogation, even were I competent to do so, to dwell upon Prof. Huxley's claims to so great an honour, whether as a profound scientific investigator of the first rank, as a teacher, or as a public servant; but I may be allowed to indicate a parallelism between his career and those of two of the eminent naturalists to whom I have alluded, which appears to me to afford an additional argument in favour of retaining his statue in proximity to theirs. Sir Joseph Banks, Mr. Darwin and Prof. Huxley all entered upon their effective scientific careers by embarking on voyages of circumnavigation for the purpose of discovery and research under the flag of the Royal Navy. Sir Joseph Banks and Prof. Huxley were both Presidents of the Royal Society, were both trustees of the British Museum; and, what is more notable by far, so highly were their scientific services estimated by the Crown and their country, that they both attained to the rare honour of being called to seats in the Privy Councils of their respective Sovereigns.

With these few words I would ask your Royal Highness graciously to accede to the prayer of the subscribers to this statue, and receive it on behalf of the trustees of the British Museum.

He was followed by Sir Michael Foster, who pronounced the following *éloge* on Huxley's work and influence:—

MAY IT PLEASE YOUR ROYAL HIGHNESS,—Before you unveil this statue it is my duty and privilege to add a few words to those which have just been spoken by the beloved Nestor of biological science. Sir Joseph D. Hooker, born before Huxley was born, a sworn comrade of his in the battle of science, standing by him and helping him like a brother all through his strenuous life, may perhaps be allowed to shrink from saying what he thinks of the great work which Huxley did.

We of the younger generations, Huxley's children in science, who know full well that anything we may have been able to do springs from what he did for us, cannot on this great occasion be wholly silent.

Some of us have at times thought that Huxley gave up for mankind much which was meant for the narrower sphere of science; but if science may seem to have been thereby the loser, mankind was certainly the gainer; and indeed it was a gain to science itself to be taught that her interests were not hers alone, and that not by one tie or by two, but by many was her welfare bound up with the common good of all.

To many perhaps the great man whose memory we are here met to honour was known chiefly as the brilliant expositor of the far-reaching views of that other great man who through his statue is now looking down upon us. Your Royal Highness is doubtless at this moment thinking of that interesting occasion, fifteen years ago, when you unveiled that statue of Darwin, and you are calling to mind the weighty words then spoken by him whose own statue brings us here to-day.

Huxley it is true fought for Darwin, and indeed "he was ever a fighter." But he fought not that Darwin might prevail; he fought for this alone—that the views which Darwin had brought forward might be examined solely by the clear light of truth, untroubled by the passion of party or by the prejudice of preconceived opinion. As he never claimed for those views the infallibility of a new gospel, so he always demanded that they should not be peremptorily set aside as already proved to be wrong.

Huxley worked for his fellow men in many ways other than the way of quiet scientific research. Had we not known this we should have thought that his whole life had been given up to original scientific investigation, so much has the progress of biologic science, since he put his hand to it, been due to his labours. On the sands of many a track of biologic inquiry he has left his footprint, and his footprint has ever been to those coming after him a token to press on with courage and with hope. The truths with which he enriched science are made known in his written works; but that is a part only of what he did for science. No younger man, coming to him for help and guidance, ever went empty away; and we all—anatomists, zoologists, geologists, physiologists, botanists, and anthropologists—came to him. The biologists of to-day, all of us, not of this country alone, but of the whole world of science, forming, as it were, a scattered fleeting monument of this great man, are proud at the unveiling of this visible lasting statue here.

In conclusion, Sir M. Foster, facing the Prince, added the words:—May I crave your Royal Highness's permission to seize this opportunity to assure you incidentally, but none the less from the bottom of our hearts, on the part of men of science that we, in common with all Her Majesty's subjects, are rejoicing that you escaped the dreadful peril to which a few days back you were exposed, and to express to you our continued esteem and respect?

On Sir M. Foster's return to his seat among the committee, the Duke of Devonshire, speaking from in front of the veiled statue, said he had the honour nearly five years ago of presiding over the committee formed for the purpose of establishing a memorial to Prof. Huxley. He had now to report to his Royal Highness that the labours of that committee had terminated, and to say that the committee desired to present the statue to his Royal Highness on behalf of the trustees of the British Museum. They felt, however, that the real memorial to the deceased man of science was to be found in the writings which had already been referred to, and still more in the scientific work he accomplished or helped to promote, and in the influence he exercised and was still exercising upon the minds of younger men, many of whom they trusted might at some future time emulate his distinguished example. On behalf the committee he begged to tender his Royal Highness their thanks for having come to give a final sanction to their proceedings, and for having undertaken the duty of unveiling the statue that day.

The Prince of Wales then withdrew the covering from the statue, and brought the proceedings to a close with the following words:—

MY LORDS, LADIES AND GENTLEMEN,—I consider it a very high compliment to have been asked by the Huxley Memorial Committee to unveil and receive this statue, and to do so in the name of the trustees of the British Museum, of whom I have the honour to be one. I have not forgotten that fifteen years ago I performed a similar duty in connection with the fine statue of the celebrated Charles Darwin, which is at the top of the stairs, when it was similarly handed over to the British Museum. We have heard to-day most eloquent and interesting speeches with reference to that illustrious man of science and the great thinker, the late Prof. Huxley. It would, therefore, be both superfluous of me, I may even say unbecoming in me, to sound his praises here in the presence of so many men of science, who know more about all his work than I do. I can only, on my own behalf, endorse everything that has fallen from the lips of those gentlemen who have spoken, and I beg to repeat the expression of the great pleasure it has given me for the second time to have performed the interesting ceremony of taking over the statue of another great and illustrious man of science.

The statue is a colossal seated one of white marble, the figure being represented in a doctor's gown, with the right hand clasping one arm of the chair, and the left lying across the other with the fist clenched. The pedestal is of Verona marble on a black base, and bears upon its face the name and dates of birth and death in simple bronze letters.

The statue is a thoroughly successful work of art, and stands out in bold relief to the dim mystery of the recess in which it is placed. Though the expression of the face is perhaps a little severe, the features are true to nature; and when it is considered that the artist was never privileged with a sitting in life, and that the only material available to him were the death mask and an assemblage of none too favourable photographs, it must be admitted he has done well. Great praise must be given to the modelling of the hands, in which those who knew the great philosopher intimately will recognise a faithful portrayal of well-defined characteristics.

The first and main object of the Memorial has thus been successfully achieved. As for those which remain, the award at the Royal College of Science is to be known as the "Huxley Gold Medal," for the "promotion of science in the directions in which Huxley was distinguished," and especially for research to be carried on in the laboratory which bears his name. It has been further arranged that the use of the obverse die shall be granted to the Anthropological Institute (of which Huxley was practically the founder), in connection with the establishment by that body of a Huxley Lectureship, and a medal, for which they will furnish the reverse. Huxley's labours as an anthropologist are among the most important of his scientific career, and it may be questioned whether his "Man's Place in Nature," published against the advice of some of his friends, who feared his "ruin" did it appear, does not now rank among the best and most enduring of his works. His influence as an anthropologist was great, and devotees to that branch of science will hail with satisfaction this decision to perpetuate his memory.

---

## PRELIMINARY NOTES ON THE RESULTS OF THE MOUNT KENYA EXPEDITION, 1899.

THE Mount Kenya Expedition left Nairobi, the then head of the Uganda Railway, on July 26, 1899, and returned to Naivasha, a station on the Uganda Road, on September 29. Considerable difficulties were experienced in the matter of commissariat, on account of the drought and famine prevalent throughout East Africa. For this reason a longer sojourn on the mountain would have been impracticable, even if other circumstances had permitted of it.

Previous accurate knowledge of Mount Kenya rested chiefly on the work of Captain G. E. Smith, R.E., who had fixed the position of the peak, by triangulation along the Uganda Road, and of Dr. J. W. Gregory, who, in 1893, ascended the south-western slope to a height which appears to have been nearly 16,000 feet. An account of the 1899 journey is given in the May number of the *Geographical Journal*.

Mount Kenya is a vast flattened dome, seered with radiating valleys. It rises from a plateau, the level of which is 5000 to 7000 feet above the sea. Upon the crown of the dome is a precipitous pyramid, the cleft peak of which has an altitude of 17,200 feet. The entire *massif* measures about fifty miles from east to west and forty miles from north to south. Its northern slopes are crossed by the equator.

We made a plane table survey of the central portion of the mountain, and connected it by route surveys with Nairobi and Naivasha. The altitude of the central peak was determined by boiling point and theodolite, combined in four different ways, with an average result practically the same as that obtained by Captain Smith at a distance of ninety miles.

The central pyramid is the core of the denuded and dissected volcano, a fact first suggested by the late Joseph Thomson, who saw the mountain from the Laikipian plateau. Although not yet examined in section, the holocrystalline rock on the summit may probably be identified with the nepheline syenite obtained by Gregory at a lower level. The core must, therefore, have risen considerably above the present peak, and if allowance be made for still loftier crater-walls, the original height of Kenya may have equalled that of the still complete Kibo summit of Kilimanjaro.

The most significant point in the structure of the mountain is the fact that, while the major axis of the peak strikes west-north-westward and throws the glaciers down northern and southern slopes, the chief water-parting runs in a direction at right angles to this, past the eastern foot of the central peak, with the effect that the valleys are thrown off eastward and westward, and that all the existing glaciers belong to the westward drainage. From a series of rock specimens obtained at widely separated spots on the summit of the craggy ridge constituting the divide, it appears that the lie of the water-parting has been determined by a system of great dykes, which must almost have split the mountain in two.

There are fifteen existing glaciers, of which two are a mile in length, and the remainder are small. Their lower ends descend to about 14,800 feet. Everywhere and at all hours at the time of our visit the surfaces were dry and crisp. Comparatively little water flowed from them, and the stream banks below gave small indication of floods. The ice was intensely hard, and fed by fine hail rather than snow. These facts may be explained by the meteorological conditions. Although the air-temperatures were not very low at night, there was then great radiation into the cloudless sky. In the afternoon, on the other hand, a cloud cap regularly warded off the sunshine. The air was usually dry, the relative humidity falling on more than one occasion to 54 per cent.

Evidence of past glaciation was frequent down to 12,000 feet both in the eastern and western valleys, and there were occasional traces down to about 9000 feet. The whole of the central part of the mountain, with the exception of the peak and the dividing ridge, must have been buried under a sheet of glacier, more than comparable to that of Kilimanjaro, at a time later than the erosion of the existing valleys.

Snow was absent from the summit, and several species of brilliantly coloured lichen were collected there. Everlasting flowers grew in the rock chinks up to 16,500 feet. In the upper Alpine zone were two distinct species of giant groundsel and two of giant lobelia, seeds of which have been brought home. The greater part of our dried plants was lost, but the mosses and lichens were saved. A series of photographs of the Alpine vegetation in various stages of growth was taken by my colleague, Mr. C. B. Hausburg.

Mr. Oldfield Thomas has described, before the Zoological Society, the skulls and skins of the mammals collected by us. The most interesting is a new species of Rock Dassy (*Procavia Mackinderi*), whose nearest relative has recently been sent home from the Eldoma Ravine by Mr. F. J. Jackson (*P. Jacksoni*). Apart from these two species, no Rock Dassies have been found in any part of East Africa, nor are they known further south. *P. Mackinderi* appears to be isolated above the forest-zone (7000–10,000 feet) on Mount Kenya. A new Forest Dassy was obtained from a lower level.

Kenya Peak, from the south-west.

The collection of birds has been described by Dr. Bowdler Sharpe. It includes a new eagle owl, as large as the European species, which feeds on the rats of the Alpine zone of Kenya, and there are three other new species. Generally the birds are similar to those of Mount Elgon, and in a lesser degree to those of Kilimanjaro. This is strikingly indicated by the fact that if Mr. Jackson had not explored Mount Elgon in 1890, nearly every bird we obtained would have been new.

The few human inhabitants of Kenya are Wandorobo, elephant hunters, who live in the forest up to its higher limit. On one occasion a party of them was seen at over 12,000 feet.

To west of Mount Kenya is the so-called Aberdare Range, traversed for the first time by the members of our expedition. It consists of two much denuded volcanic stumps, Nandarua and Sattima, rising to 12,900 and 13,200 feet respectively, and of a raised block, 9000 feet high, defined by parallel fault scarps, which strike in the same direction as the scarps of the Great Rift Valley. This mountain block and the Rift Valley may be the necessary complements of one another.

Only a small collection of insects was obtained, chiefly in Kikuyu, but Prof. Poulton informs me that it includes new species of Coleoptera, Forficulidæ and Hymenoptera.

H. J. Mackinder.

---

## THE DUKE OF ARGYLL.

Among the losses which science is from time to time called upon to deplore, not the least serious arise from the death of men of prominent public position who have taken an active personal interest in the advance of natural knowledge, and have done their best to promote it. The late Duke of Argyll was an eminent example of this type of man. Heir of a long line of illustrious ancestors, who for many generations have played a leading part in the stormy annals of their native country, called early in life to the legislature where he mingled conspicuously in the political conflicts of his time, full of wide and generous sympathies which prompted him to speak or to write on most of the great questions that agitated the public mind during his long and brilliant career, the Duke yet found time to read much and widely in science, and to keep himself acquainted with the progress of scientific discussion and achievement. He was happily gifted with a marvellous versatility, so that he could turn rapidly from one sphere of thought and activity to another far removed. Hence, amid the cares of State and of the administration of a great domain, as well as in the sorrow of domestic bereavement, he was often to be found immersed in the perusal of some recent treatise, or carrying on a research of his own in those parts of the scientific field which more specially interested him. Whether as an acute critic of the labours of others, or as an observer of nature himself, his devotion to these pursuits remained a characteristic feature of his life from the beginning to the end. It is difficult at present to define with precision the extent and value of the services of such a man in the progress of the science of his time. His own original contributions may be little in amount or importance, but his example and his enthusiasm, together with his political activity and his social rank, combine to make him a force in the land, which powerfully aids any good cause which he espouses. The death of the Duke of Argyll is thus an event which must be chronicled with sincere regret in the pages of a scientific journal.

It was through geology that the Duke first came practically in touch with science, and it was in geological pursuits and criticisms that he found the most congenial employment of his leisure moments. It is just half a century since, on a visit to his property in the Island of Mull, he found that one of his tenants had gathered a number of fossil leaves and plants from the rocks of the neighbourhood. At once appreciating the geological significance of these remains, he investigated their mode of occurrence, and recognised their association with sheets of lava and volcanic ashes. The plants were pronounced by Edward Forbes to be probably of Miocene age, and thus was securely laid the first stone of the edifice that has since been reared in illustration of the volcanic history of the Inner Hebrides. It is matter for regret that the Duke never followed up this important discovery.

Other geological fields attracted him, where he found ampler material for the exercise of that critical acuteness and the display of that forensic style of argument which made his writings so lively and so pungent. He had imbibed his earliest ideas of geological causation in the school of the cataclysmists, and to these ideas he adhered to the last. When the earlier views of Hutton and Playfair with regard to the denudation and sculpture of the land were revived and began to spread among the younger men, the Duke raised his protest against them, and poured on them the contempt and ridicule which they seemed to him to deserve. As they grew in acceptance, both in this and other countries, and as their advocates increased in number and in confidence, his vehemence of declamation seemed to augment in proportion.

Nor was this the only line along which the modern tendency in geological speculation seemed to the Duke to be running in an entirely wrong direction. When he began to interest himself in these questions, Agassiz' doctrine, that not only Britain but a large part of Europe was once buried under land-ice, had not been generally accepted. The geologists of this country preferred to account for the phenomena by supposing that the land had been submerged in a sea across which floating ice drifted. The Duke of Argyll was never able to accept the modern doctrine, except in a limited degree. He admitted the former existence of local valley-glaciers, but could not recognise the force of the evidence adduced to show that not only the valleys, but the surrounding hills had once been over-ridden by a vast sheet of ice.

The rise of the modern school of evolution afforded the Duke full scope for the exercise of his acute reasoning power and keen critical faculty. In article after article, address after address, and volume after volume, he subjected the doctrines of that school to the closest scrutiny. It may be freely admitted that he detected here and there a fallacy, and pointed out a conclusion different from, but not less probable than, that which his opponents had drawn. But perhaps his most valuable service lay in that border-land of philosophy and science in which he specially loved to exercise his thoughts and his pen. Even when men of science differed widely from his his conclusions, they could not but admit that in his "Reign of Law" and his "Unity of Nature," he showed the wide range of his reading, the clearness and vigour of his reasoning powers, the force and eloquence of his style, the grasp he had of some of the more difficult scientific problems of his day, the strong bent of his nature towards metaphysics, and, above all, the lofty tone of his sentiments in regard to the moral nature and destiny of man.

The Duke of Argyll was essentially a man of action, to whom the stir of conflict and the stimulus of controversy were not uncongenial. Even in his scientific discussions he could not always quite forego the style in which he vilipended the opposite party in the House of Lords or in the public prints. He seemed sometimes hardly to realise the full extent and meaning of the evidence which he was criticising. In conversation, indeed, he might appear for a time to be impressed by the force of this evidence, and be willing to admit that the truth might, perhaps, lie somewhere between his own views and those to which he was opposed. But the force of early conviction or prepossession would, in the end, be too strong for him, and possibly the next morning his opposition would be found to be as complete and confident as ever. Unflinching and resourceful as an antagonist, enforcing with almost passionate enthusiasm what he held to be the truth, independent and self-reliant alike in his opinions and his actions, dignified and courteous after the manner of an older time, he formed altogether a striking and picturesque personality.

But the energy of the doughty debater was combined with much personal kindliness even towards those from whom he most seriously differed. Above all the other features of his character there shone out an intense love of nature and an eager desire to know more of her processes and laws. Year after year the Duke would spend weeks at a time in his yacht among the Western Isles, which he loved with all the enthusiastic devotion of one who was born and spent his youth among them. He was familiar with that western coast from one end to the other, under every change of sunlight and shadow. He had sketched every peak and crag and island, and he delighted to recall from his sketch-books the charm with which these scenes had fascinated him. To all their obvious attractions for the ordinary visitor his geological knowledge enabled him to join the fresh interest which is given to them by an acquaintance with the history of their remote past. In this way he kept himself in touch with some of the aspects of nature that most vividly appealed to his imagination. His poetic temperament found refreshment in these frequently renewed sojourns amid the varied scenery of the West of Scotland. As shown by his published writings, his wide acquaintance with modern English poetry furnished him with many an apt quotation and allusion. Tennyson's poetry seemed to be particularly familiar to him, insomuch that a casual citation of a line or expression from that poet by one of the company would sometimes lead the Duke to quote from memory the whole passage.

As the head of a great historic clan, the Duke of Argyll was a true Scot, who had studied his country's history both geological and political, and had made himself personally acquainted with a large part of its surface. The geological problems that more particularly engaged his attention were largely those which his own Highland hills and glens had suggested to his mind. Now and then, in the midst of an eager conversation, a Scottish word or expression would come most readily to his lips as conveying the meaning he wished to express. Of his general services to the country at large this is not the place to speak. But we may confidently anticipate that when some future historian shall review the various forces which have furthered the advance of science in this country during the Victorian age, a well-marked place will be assigned to the services rendered by the Duke of Argyll.

A. G.

## PROF. A. MILNE-EDWARDS.

IT is with sincere regret that we have to record the death, at the age of sixty-four, of Prof. Alphonse Milne-Edwards, the Director of the Paris Museum of Natural History, which took place at Paris on Saturday, April 21, after a brief illness. The late professor was of English descent, being the grandson of Mr. Bryan Edwards, M.P., a West Indian planter who settled at Bruges; and, with this ancestry, it is curious to note how extremely imperfect was his colloquial knowledge of the English language. His father, Prof. Henri Milne-Edwards, was the well-known eminent zoologist of Paris, who died in 1885; and father and son were for many years associated in zoological work.

Born in Paris in 1835, Alphonse Milne-Edwards took his medical degree in 1859, and was nominated Professor at the School of Pharmacy in 1865. In 1876 he acted as deputy for his father as Professor of Zoology at the Jardin des Plantes; in the following year he succeeded the late Prof. P. Gervais as a member of the Institute of the Paris Academy of Sciences; and in 1885 he entered the Academy of Medicine. In 1891, being already Professor of Zoology, he was appointed Director of the Paris Museum of Natural History and of the Menagerie in the Jardin des Plantes; his official title as regards the latter post being *Administrateur chargé de la Direction de la Ménagerie au Musée d'Histoire naturelle*.

Having published, in 1864, an important memoir on the anatomy and affinities of the Chevrotains, and a second, in 1866, on the osteology of the Dodo, in 1867 Milne-Edwards issued the first fasciculus of his magnificent work, entitled "Recherches Anatomiques et Paléontologiques pour servir à l'Histoire des Oiseaux Fossiles de la France," which was completed in four volumes (two of text and two of plates) in 1872. As mentioned by Prof. A. Newton, this monumental work marked an epoch in ornithology, for it showed the possibility of forming a classification of birds by means of their "long bones." Much interest was excited by the identification in this work of remains of peculiar existing African and Malagasy genera of birds in the French Tertiaries. While this work was in progress, Alphonse Milne-Edwards was associated with his father in bringing out the "Recherches pour servir à l'Histoire naturelle des Mammifères," which was commenced in 1868 and completed in 1874. A large proportion of the latter was devoted to the description of new types of mammals from Central Asia, among them being the many strange forms, like *Aeluropus*, then recently obtained by Père David in the Moupin district of Eastern Tibet. The period from 1866 to 1874 also saw the issue of "Recherches sur la Faune ornithologique éteinte des Îles Mascareignes et de Madagascar." And the late professor's interest in the Malagasy fauna was likewise shown in a paper on the embryology of the Lemurs, published in 1871, and in his contributions to Grandidier's "History of Madagascar," still in course of publication.

But it would be a mistake to suppose that the researches of Prof. Milne-Edwards were by any means restricted to mammals and birds. From an early period in his career his attention had been directed to the study of zoophytes and crustaceans; and later on he had attentively studied the animals adherent to submarine cables, which had been raised after a sojourn at the bottom of the sea. With this latter subject the study of the ocean floor was intimately connected. And in 1880 he brought before his Government the advisability of fitting out an expedition for submarine surveying, with the result that in the following year a party of savants, under his own direction, embarked on the *Travailleur* to survey the Gulf of Gascony. The results obtained were so important that the same vessel was again put at the disposal of the professor, who completed the survey of the Gulf of Gascony, and explored the sea-bottom of the Strait of Gibraltar and of a considerable portion of the Mediterranean. In 1882 the *Travailleur* undertook a surveying voyage of the Atlantic as far as the Canaries. The year following the *Talisman* took the place of the *Travailleur*, and carried Prof. Milne-Edwards and his associates to the coasts of Portugal, Morocco, and the Canary and Cape Verde Islands, and then on to the Sargasso Sea, whence it returned by way of the Azores. The results of these dredging expeditions were published under the title of "Expéditions scientifiques du *Travailleur* et du *Talisman* pendant les années 1881, 1882 et 1883."

For these deep-sea explorations, Milne-Edwards was awarded the gold medal of the Royal Geographical Society. In 1876 he was elected a Foreign Member of the Zoological Society of London, and in 1882 a Foreign Correspondent of the Geological Society. He paid several visits to England, the last on the occasion of the Zoological Congress at Cambridge in 1898. R. L.

---

## NOTES.

THE funeral of the Duke of Argyll will take place at the family burial ground, Kilmun, on the Holy Loch, on Tuesday next, May 8.

THE annual conversazione of the Institution of Electrical Engineers will be held at the Natural History Museum, South Kensington, on Tuesday, June 26.

THE Duke of Cambridge, president of the Sanitary Institute, will occupy the chair at the Institute dinner on Friday, May 11.

THE University of Göttingen has awarded the Volbrecht prize for scientific research to Dr. Gegenbauer, professor of anatomy at Heidelberg. The prize is of the value of 12,000 marks (600*l.*)

To commemorate the foundation of the k. k. geologischen Reichsanstalt of Vienna, in 1849, a jubilee meeting will be held in the great hall of the Institute on June 9, and representatives of science or of scientific institutions are invited to be present.

THE *Botanical Gazette* records the death by drowning, in September last, of Prof. Kyokichi Yatabe, the founder of the Botanical Society of Japan.

THE annual meeting of the American Association for the Advancement of Science will be held at Columbia Universtity, New York, from June 25 to June 30.

WE learn, from the *American Naturalist*, that the herbarium and the principal part of the botanical library of Columbia University have been transferred to the New York Botanic Garden, and that, in future, the advanced work in botany of the University will be carried on in the laboratory of the Garden.

THE *British Medical Journal* states that the tenth award of the Riberi prize of 20,000 lire (800*l.*) will be made by the Royal Academy of Medicine of Turin on December 31, 1901, for the best printed or manuscript work, or the most important discovery, during the quinquennium 1897–1901, in the domain of experimental pathology, hygiene, or forensic medicine.

THE Franklin Institute has awarded John Scott medals and premiums to Mr. A. V. Groupe for his improved braiding machine, to Messrs. C. A. Bell and S. Tainter for their invention of the graphophone, and to Mr. A. M. Hopkins for his pneumatic system for preventing the bursting of water-pipes by freezing. Elliott Cresson medals have been awarded to Mr.

L. E. Levy for his acid-blast method of etching metal plates; and to Prof. W. O. Atwater and Mr. E. B. Rosa for their respiration calorimeter.

THE *Daily News* states that Lieut. R. E. Peary has forwarded some interesting relics to the Royal Naval College, Greenwich. These consist of the sextant left behind in Repulse Harbour by Lieut. Beaumont in 1876, and subsequently recovered by Lieut. Peary, and the original record deposited in a cache by Sir George Nares on Norman Lockyer's Island in 1875. The great meteorite which Lieut. Peary brought back from his last Arctic expedition still remains on the Cob Dock of the Brooklyn Navy Yard. The meteorite weighs 200,000 pounds, and Lieut. Peary wishes to obtain 15,000*l.* for it.

THE Trinity House steam vessel *Irene*, with the deputy master, Captain G. R. Vyvyan, on board, accompanied by a committee of the Elder Brethren and their scientific adviser, Lord Rayleigh, has proceeded to the Bristol and English Channels in order that special surveys in connection with new lighthouse works, and observations on both English and French lights from seaward, may be made.

THE death is announced of Mr. G. V. Ellis, who succeeded Prof. Quain as professor of anatomy in University College, London, in 1850, an appointment which he held for twenty-seven years, resigning in 1877, when he was appointed Emeritus Professor. Mr. Ellis was co-editor with the late Dr. William Sharpey of the sixth edition of "Quain's Elements of Anatomy," published in 1856, and the author of several works for students of anatomy.

AMONG the items included in the Prussian Budget is a sum of 7,300,000 marks, for the purchase of lands in Berlin, on which is to be erected a building for the Academy of Sciences and the Royal Library. The value of the land is estimated at more than 11,000,000 marks, but about 3,000,000 marks is obtained by the exchange of other property, and 1,000,000 marks is to be voted next year.

A SUMMER meeting of the Anatomical Society of Great Britain and Ireland will be held at the Owens College, Manchester, on Thursday and Friday, June 21 and 22. Opportunities will be afforded to members of seeing things of local interest during their visit to Manchester. An excursion to the Lake District will be arranged, and members who desire to join the party are requested to inform the local secretary, Dr. Peter Thompson, the Owens College, Manchester.

A COMMITTEE composed of many eminent men of science in France has been formed for the purpose of obtaining funds for the erection of a modest monument at Langres in honour of Auguste Laurent, the renowned chemist. Laurent was born at La Folie, near Langres, in 1808, and in 1831 became assistant to Dumas, under whom he acquired a special knowledge of organic chemistry, and carried on his original researches on naphthalene and carbolic acid, together with their derivatives. After filling various posts, the last of which was a chemical professorship at Bordeaux, Laurent became Warden of the Mint at Paris, where he remained in intimate connection with Gerhardt until his death in 1853. Subscriptions for the proposed monument should be sent to the treasurer of the Committee, M. Caublot, 45 rue de Belleville, Paris.

MR. JAMES MANSERGH has been elected president of the Institution of Civil Engineers, in succession to Sir Douglas Fox. Sir William White, K.C.B., F.R.S., Mr Charles Hawksley, Mr. J. C. Hawkshaw, and Mr. F. W. Webb have been elected vice-presidents. The following awards have been made for papers read and discussed before the Institution during the past session:—A George Stephenson medal and a Telford premium to Sir Lowthian Bell, Bart., F.R.S.; Telford medals and premiums to Messrs. H. H. Dalrymple-Hay, B. M. Jenkin, F. W. Bidder and F. D. Fox; a Watt medal and a Telford premium to Mr. J. Dewrance; a Crampton Prize to Sir Charles Hartley; and Telford premiums to Messrs. C. N. Russell and R. A. Tatton. The presentation of these awards, together with those for papers which have not been subject to discussion, and will be announced later, will take place at the inaugural meeting of next session.

AMERICAN ethnology has been deprived of a prominent worker by the death of Mr. Frank H. Cushing. Mr. Cushing, says the *Scientific American*, was born in 1857, at Northeast, Pa., and when he was only eighteen years of age his work was brought to the attention of the late Mr. Spencer F. Baird, who was then Secretary of the Smithsonian Institution, and in 1875 he went to Washington as an assistant in that institution. He had charge of the ethnological exhibit at the Centennial Exposition of 1876, and in 1879 he accompanied an expedition from the Smithsonian Institution to investigate the Pueblos of New Mexico, and at his request was left at the Pueblo of Zuni, where he lived almost continuously for six years. He returned to Washington in 1884 and began to work up his voluminous notes. Two years later he was made Director of the Hemenway South-western Archæological Expedition. Extensive excavations were made in South Arizona and New Mexico, and the large collection of objects of prehistoric art which he gathered is in the Peabody Museum at Cambridge, Mass. This work took up two and one-half years of his time, and then Mr. Cushing returned to the United States Bureau of Ethnology to supervise a memoir on the Zuni myths printed by the Bureau. Three years later he became director of the expedition fitted out by Mrs. Phœbe A. Hearst and the late Dr. William Pepper, conducted under the auspices of the National Museum, the Bureau of Ethnology and the University of Pennsylvania.

THE motion for the second reading of the Sea Fisheries Bill in the House of Commons, on Monday, resulted in a lively discussion. The Bill prohibits the sale of flatfish below a specified size, and its rejection was moved on the grounds that it would not have the effect of preventing the destruction of immature fish, or of increasing the supply of fish. In the course of the discussion, an honourable member said that the whole of the trouble arose from the institution of a number of committees composed of farmers, lawyers, and captains of the horse, foot, and artillery, who knew little of fishing, and who ventilated strange theories and supported them with portentous and irrelevant statistics. This remark was used as an argument against the Bill, but it may also be taken to mean that if fishery matters were controlled by scientific men familiar with the natural history of the sea, and questions concerning fisheries were referred to marine biologists, recommendations would be made upon which reasonable regulations might be based. Board of Trade statistics prove that there is a large destruction of immature fish, and that the quantity of fish landed has decreased during recent years. The Government, wishing to preserve a great national industry, have put forward the present Bill, which is really the Undersized Fish Bill of last year, and has appeared under various other titles in previous years. The discussion upon the Bill was not completed when the House adjourned on Monday.

THE report presented at the anniversary meeting of the Zoological Society, held on Monday, stated that the number of Fellows of the Society at the end of last year was 3246. The total income of the Society during the past year was 28,880*l.* The average annual receipts of the Society for the previous ten years have been 26,370*l.*, so that the receipts for 1899 exceeded that average by 2509*l.* The number of visitors to the Society's

Gardens in 1899 was 696,707. The number of animals now living in the Gardens is 2753, of which 821 are mammals, 1471 birds, and 461 reptiles and batrachians. Amongst the additions made during the past year, thirteen were specially commented upon as being of remarkable interest, and in most cases new to the Society's collection. Of these, by far the most noticeable objects exhibited for the first time were the pair of Grévy's zebras placed under the care of the Society by Her Majesty the Queen. These animals, which had been presented to Her Majesty by the Emperor Menelik of Abyssinia, were brought down to Zeila, on the coast of Somaliland, under the care of Captain J. L. Harrington, the British Political Agent. At Zeila they were handed over to the Society's assistant superintendant, Mr. Arthur Thomson, who had been sent there by the Council at the request of the Foreign Office on purpose to receive them, and by him they were landed safely in London on August 14 last year. The Council also called special attention to the young male giraffe, acquired in April 1899, by purchase, for the sum of 800*l*. It is believed that this animal, together with the female purchased in 1895, form the only pair of young giraffes now to be found in any of the zoological gardens in Europe. The works in connection with the new bore at the well and the new machinery for pumping were completed last year. The new water supply has been further improved by the construction of a second and larger reservoir, so that an excellent supply of water will henceforth always be available in every part of the Gardens.

MR. F. W. HASELGROVE sends us a photograph of a robin's nest in a water-can, with the bird sitting upon its eggs, now to be seen at Finchley Cemetery. Robins are well known to build their nests frequently in curious places, one of the most remarkable instances on record being that of a nest in a battered beer-can between the rails over which trucks were continually passing at Worthing railway station. Flower-pots and water-cans appear to be favourite nesting-places of the birds.

THERE are reasons for believing that the Scandinavians discovered America and settled in Massachusetts in pre-Columbian days. The evidence consists in the occurrence of certain ruins which correspond closely with ruins of the Saga-time in Iceland, but which differ from native dwellings and early European ruins on the coast; and also in the correspondence in the physical features of the Massachusetts coast with the description of the country called Vinland in Icelandic literature. This evidence has recently been brought together in an illustrated article by Miss Cornelia Horsford in *Appleton's Popular Science Monthly*.

THE recent Norwegian earthquakes are studied by Mr. J. Rekstad in a paper published in the *Bergens Museums Aarbog* (1899, No. iv.). During the four years 1895–1898, the number of recorded earthquakes is 77, the corresponding number for Great Britain being 24, and for Greece, 1652.

A SLIGHT earth-shake occurred near Manchester at about 1.17 a.m. on April 7. It was felt at Pendleton, Pendlebury, Seedley, Salford and other places in the immediate neighbourhood of the Irwell Valley fault. The small disturbed area and the rather marked intensity of the shock point to a local origin, probably connected either directly or indirectly with the extensive coal-workings of the district. On February 27, 1899, a similar earth-shake was felt at the same places (see NATURE, vol. lxi. p. 546).

WE have received a reprint of a paper, published in the *Bulletin* of the Geographical Society of Philadelphia, "On the Nicaragua Canal in its Geographical and Geological Relations," by Prof. Hugelo Heilprin. The paper, which is illustrated by maps and photographs, discusses (1) the volcanic phenomena of the region of the proposed canal; (2) an assumed inconstancy in the level of Lake Nicaragua; and (3) the deformation of the Nicaragua coast-line. After pointing out the marked deficiency of trustworthy information concerning the region, especially with regard to lake and river topography and hydrography and dynamical geology, the author concludes that "the facts that are known render doubtful, or at least open to question, the advisability of constructing, or even the practicability, of a canal such as is contemplated." . . . "It may, perhaps, be properly questioned whether, if the canal had been constructed a hundred years ago, along the site that is now being contemplated, it would be in existence to-day."

THE current number of *La Geographie* contains a suggestive paper on the variation of the limits of the Mediterranean region, by M. Gaston Bonnier. It is pointed out that attempts to define the boundary from geological considerations have proved unsatisfactory, and that the region is more clearly distinguished by its climate. This may be traced in the flora, the Mediterranean region being roughly taken in France as the region of the olive. M. Bonnier contends that it can be more closely followed, especially in certain regions, by reference to other plants, and discusses a number of interesting observations with regard to exposure and elevation.

AT the close of an address recently delivered as president of the Anthropological Society of Washington, Mr. W. J. McGee enunciated the cardinal principles of science as follows:—"The indestructibility of matter, the contribution chiefly of chemistry; the persistence of motion, the gift mainly of physics; the development of species, the offering of the biotic sciences; the uniformity of nature, the guerdon of geology and the older sciences; and the responsivity of mind, the joint gift of several sciences, though put in final form by anthropology." These principles are comprehensive enough, but they will not satisfy all students of epistemology, so much depends upon the point of view occupied.

THE manufacture of silk cord from spiders' web seems likely to attain commercial importance, for we learn through the *Board of Trade Journal* that one of the most novel exhibits in the Paris Exposition will be a complete set of bed-hangings manufactured in Madagascar from the silk obtained from the halabe, an enormous spider that is found in great numbers in certain districts of the island. The matter has been taken up by M. Nogue, the head of the Antananarivo Technical School. The results he has already achieved show that the production of spider silk should quickly become a highly important industry. Each spider yields from three to four hundred yards of silk. After the thread has been taken from the spiders they are set free, and ten days afterwards they are again ready to undergo the operation. The silk of these spiders, which is of the most extraordinary brilliant golden colour, is finer than that of the silkworm, but its tenacity is remarkable, and it can be woven without the least difficulty.

We have received from the Agricultural Department of the Economical Society of Youriev (Dorpat) a report upon the results of rainfall and temperature observations made in the Baltic Provinces of Livonia and Esthonia during 1898. This is the thirteenth year of publication; the report contains a large amount of very useful statistics, including monthly and yearly means and the number of rainy days at no less than 203 stations. The same information is also shown very clearly in a graphical manner, together with a comparison of the year's results with a ten years' average. We note that the publication of the results for the year 1899 may be expected very shortly.

The Weather Bureau of the United States has published a valuable discussion of the climate of San Francisco (*Bulletin* No. 28), by Messrs. A. G. McAdie and G. H. Willson. The work is based upon observations collected during the last thirty years, and the results are given in considerable detail on account of the important position of the town and the peculiarity of its climate. The authors state that if a native of San Francisco were asked which was the coldest month of the year, he might be unable to answer, and if asked which was the warmest, he might say November. This arises from the comparative small range of temperature; the mean annual temperature is about 56·2°. May and November have practically the same temperature; the warmest month is September, 60·9°, and the coldest January, 50·1°. The highest temperature recorded was 100°, in June, 1891, and the lowest 29°, in January, 1888. The mean of the three consecutive warmest days has never exceeded 76·3°, and the mean of the three coldest days was 40·7°. The annual rainfall is 23 inches. July and August are practically without rain, while December and January together have nearly 10 inches.

A series of Lower Silurian fossils from Baffin Land, in the region between Hudson Bay and Davis Strait, has been described and figured by Mr. Charles Schuchert (*Proc.* U.S. Nat. Museum, vol. xxii. 1900). The fossils belong to the Trenton group, and the strata rest unconformably on old crystalline rocks. The author notes the early introduction in the Baffin fauna of Upper Silurian genera of corals, such as *Halysites*. He also remarks that the corals, brachiopods, gasteropods and trilobites have a wide distribution, and are less sensitive to differing habitats than the cephalopods or lamellibranchs.

In an article on the Dwyka Coal-measures (*Trans.* S. African Phil. Soc. vol. xi.), Mr. E. J. Dunn points out that the Dwyka conglomerate, which occurs at the base of the coal-bearing series, is a most valuable horizon, and that its length of outcrop exceeds 2000 miles. This is shown on an accompanying map. Within this outcrop coal *may be present* at varying depths over an immense area, extending from the southern part of the Transvaal to Kimberley and near East London. Borings alone can decide if profitable seams occur, and if so, at what depths.

It is well known that the blood of animals that have been poisoned with carbonic oxide loses its power of absorbing oxygen. Dr. Adolfo Moutuori, writing in the *Rendiconto* of the Naples Academy, describes experiments tending to explain the fact that dogs are capable of surviving the injection into their veins of a quantity of carbonic oxide far greater than would poison them if inhaled. It is found that the poisoned blood reacquires its power of absorbing oxygen when it is brought into contact with the pulmonary tissues, but not otherwise.

The statics and dynamics of pseudospherical space in three dimensions form the subject of a memoir by Prof. D. de Francesco in the *Rendiconto* of the Naples Academy. Defining the co-ordinates of a point as the hyperbolic sines of the perpendiculars on three principal orthogonal planes of reference, the author introduces the conception of the moment of a force with regard to a point, analogous to the moment in ordinary statics, and, in addition, the new notion of the co-moment, of which an analytic expression is given. By representing forces by the hyperbolic sines of segments measured on their lines of action the equation of virtual work is established, and by applying this equation to a rigid system the author determines the six characteristics, the central axis, and the invariants. Starting from the conception of the co-moment, the problem of dynamics is treated by the method of Poinsot. Two invariants are found, and the conditions for their vanishing lead to remarkable geometrical properties, which do not exist in ordinary mechanics. The same author discusses in the *Atti dei Lincei* the kindred problem of integration of the differential equations of free motion of a rigid body in space of constant curvature.

Mr. J. E. Griffith, of Bangor, author of the "Flora of Carnarvonshire and Anglesey," proposes to publish a series of photographic reproductions of the cromlechs of these two counties of Wales. The series will contain forty-three photographs of thirty-six different cromlechs.

A rumoured project of reclaiming Wicken Fen in Cambridgeshire, forming the subject of a recent leader in the *Standard*, once more raises the question as to the desirability of acquiring by public subscription this last remaining habitat of the old fauna and flora of the Fen district, and thus saving them from extinction. Such a project was suggested some time ago by Mr. Carrington, the editor of *Science Gossip*, and it is much to be hoped that a movement may be set on foot for the purpose before it is too late.

We have received No. 3 (vol. i.), for April, of *Climate*, "a Quarterly Journal of Health and Travel," edited by Dr. C. F. Harford-Battersby. The periodical is the organ of the Travellers' Health Bureau, the object of which is to supply to inquirers information of every kind connected with the health and comfort of travellers and of residents in unhealthy climates. Among the original articles in the number before us is a very interesting one on "Gardening in West Africa," by Miss Kingsley, and a *résumé* of the facts at present ascertained connecting malaria fever with the parasite of the mosquito. A short paper on "European Children in Tropical Climates," by Dr. G. D. McReddie, will be read with interest by many.

A "Flora of Bournemouth" is announced for early publication by the Rev. E. F. Linton, of Bournemouth (subscription price, 7*s.* 6*d.*). The area taken is a radius of twelve miles, and includes portions of the counties of Hants and Dorset, with the Isle of Wight. The total number of flowering plants and Pteridophytes is stated as 1137.

In the *Naturwissenschaftliche Wochenschrift* for April 15, Prof. M. Möbius gives an interesting account of pigments in the vegetable kingdom. Commencing with the colouring matters of fungi and lichens, he proceeds to those in the various groups of Algæ, and then to the pigments of Muscineæ, Pteridophytes, and Phanerogams, contained in the stem, root, leaves, flowers, and fruits. He regards chlorophyll and hæmoglobin as antagonistic substances, the one characteristic of the vegetable, the other of the animal kingdom.

To the *Sitzungsberichte* of the Berlin Academy for March 15, Dr. K. von Möbius, the director of the Zoological Museum, communicates a suggestive paper on our perception of the æsthetic proportions of various mammals.

THE April number of the *Journal of Anatomy and Physiology* contains the full text of the paper read by Dr. Albert Gray at the last meeting of the British Association on Helmholtz's theory of hearing. The author proposes a modification of the theory of the German investigator, according to which a remarkable analogy between the senses of hearing and touch is shown to exist.

IN the last issue of the *Transactions* of the South African Philosophical Society, Dr. R. Marloth gives the results of his investigations as to the mode of growth of the barnacle infesting the Southern Right Whale. Were it not for some special provision, the growth of the epidermis beneath, coupled with the wearing away of the outer layer, would soon cause the parasite to be shed, and, as a matter of fact, this actually takes place with the dead shells. The living barnacle cannot, however, be discarded in this manner, since it dissolves the part of the epidermis with which its skin is in contact at the same rate at which fresh epidermal tissue is formed below. Consequently the layer of epidermis between the barnacle and the true skin never varies in thickness, and the parasite accordingly retains its position, the shell disintegrating at the apex at the rate at which it grows at the base.

MM. GAUTHIER-VILLARS, Paris, have published the third revised edition of the "Traité élémentaire d'Electricité avec les principales Applications," by M. R. Colson.

MR. FELIX L. DAMES, Berlin, has issued a catalogue of books and papers on astronomy, geodesy, meteorology and related sciences, which he has acquired from the library of the late Dr. H. Romberg, and offers for sale.

THE seventh edition of the late Prof. Milnes Marshall's well-known and practical manual on "The Frog: an Introduction to Anatomy, Histology, and Embryology," edited by Dr. G. Herbert Fowler, has been published by Mr. David Nutt. The chief addition consists of a new series of woodcuts in illustration of the development and metamorphosis of the frog.

THE "Handbook of Jamaica," compiled by Mr. T. L. Roxburgh and Mr. J. C. Ford, and published by Mr. Edward Stanford, is filled with historical, statistical and general information concerning the island. We notice that the magnetic declination, which was 6° 30′ E. at the end of last century, and has been steadily decreasing since then, is now only 1° 24′ E., and in 1910 its value will be zero.

IN the course of a few weeks, Mr. Gustav Fischer, Jena, will commence the publication of "Aus den Tiefen des Weltmeeres," an elaborate work in which Prof. Carl Chun will describe and illustrate the German deep-sea expedition to Antarctic waters. The work will be published in twelve parts, the first of which will appear during this month and the last in November.

A SIXTH edition, revised and enlarged, of "A Text-book of Assaying," by C. and J. J. Beringer, has just been published by Messrs. Charles Griffin and Co. Mr. J. J. Beringer is responsible for the revision of this handy book for assayers; and he remarks in the preface: "The principal changes in this edition are additions to the articles on gold, cyanides and nickel, and a much enlarged index. The additional matter covers more than forty pages."

SCIENTIFIC students and investigators in Melbourne should be grateful to Mr. T. S. Hall for the "Catalogue of the Scientific and Technical Periodical Literature in the Libraries in Melbourne," which he has prepared. Besides periodicals, the list includes reports of scientific societies, as well as Government reports and Parliamentary papers of scientific import. The catalogue will be a very useful guide to scientific literature accessible in Melbourne and its suburbs.

THE sixteenth part of Mr. Oswin A. J. Lee's fine work, "Among British Birds in their Nesting Haunts, illustrated by the Camera," has just been published by Mr. David Douglas, Edinburgh. The birds illustrated and described are the blackcap, bullfinch, short-eared owl, yellow wagtail, stock dove, pintail, wryneck, and lesser whitethroat. The present part completes the fourth volume, and it is hoped that the whole work will be finished in the course of a few months.

AT the meeting of the Chemical Society on June 1, 1899, Prof. Sydney Young, F.R.S., described a series of tests made by him to determine the relative efficiency of various forms of still-heads for fractional distillation. The design of several new still-heads, superior in many respects to those in common use, was an outcome of the investigation; and chemists will be glad to know that Messrs. J. J. Griffin and Sons have now placed these improved forms upon the market.

THE additions to the Zoological Society's Gardens during the past week include a Mozambique Monkey (*Cercopithecus pygerythrus*, ♀) from Uganda, presented by Lady Ashburnham; two Leopards (*Felis pardus*, ♂ ♀) from India, presented by Mrs. C. Simpson; a Tawny Owl (*Syrnium aluco*) from Scotland, presented by Mrs. C. M. Blackwood; six Common Vipers (*Vipera berus*) from Dorsetshire, presented by Mr. A. Old; nine Natterjack Toads (*Bufo calamita*) from Norfolk, presented by Mr. J. B. Thornhill; a Sykes's Monkey (*Cercopithecus albigularis*, ♀), a Flap-necked Chameleon (*Chamaeleon dilepis*) from East Africa, a Cactus Conure (*Conurus cactorum*) from Bahia, deposited; two Gold Pheasants (*Thaumalea picta*, 2 ♀), two Silver Pheasants (*Euplocamus nycthemerus*, 2 ♀), two Cabot's Horned Tragopans (*Ceriornis caboti*, ♂ ♀) from China, two Germain's Peacock Pheasants (*Polyplectron germaini*, ♂ ♀) from Cochin China, two Japanese Pheasants (*Phasianus versicolor*, ♂ ♀), two Sœmmerring's Pheasants (*Phasianus soemmerringi*, ♂ ♀) from Japan, three White-backed Trumpeters (*Psophia leucoptera*) from the Upper Amazons, four Wonga-Wonga Pigeons (*Leucosarcia picata*) from New South Wales, a Musky Lorikeet (*Glossopsittacus concinnus*) from Australia, three Blue-crowned Hanging Parrakeets (*Loriculus galgulus*) from Malacca, an Ural Owl (*Syrnium uralense*), North-east European; a Great Wallaroo (*Macropus robustus*, ♂) from South Australia, a Barbary Wild Sheep (*Ovis tragelaphus*, ♂) from North Africa, purchased; a Yak (*Poephagus grunniens*, ♂), born in the Gardens.

## *OUR ASTRONOMICAL COLUMN.*

NEW VARIABLE IN TAURUS.—In the *Astronomische Nachrichten* (Bd. 152, No. 3635) M. W. Ceraski, of Moscow, announces the discovery of another new variable by Madame Ceraski during her examination of the plates taken by M. S. Blajko. The star's position is:—

| R.A.<br>h. m. s. | | Decl.<br>° ′ ″ | |
|---|---|---|---|
| 5 33 17·33 | ... | +26 18 58·3 | (1900) |
| 5 30 29·56 | ... | +26 17 7·9 | (1855) |

The star is not found in the B.D. At its maximum it is of 9·0–9·5 mag.; at minimum, about 12 mag. or less. On 1900 March 29, it was at the limit of visibility in a telescope of 4·5 inches aperture.

SEARCH EPHEMERIS FOR EROS.—In view of preparing for observations of this minor planet during the coming opposition, the following ephemeris has been prepared by J. B. Westhaver from the elements computed by H. N. Russell (*Astronomical Journal*, No. 479, vol. xx. p. 185).

*Ephemeris for* 12*h*. *Greenwich Mean Time.*

| 1900. | | R.A. h. | m. | s. | Decl. ° | ′ | ″ | Mag. |
|---|---|---|---|---|---|---|---|---|
| May | 3 | 23 | 2 | 0·1 | −4 | 0 | 25 | 13·4 |
| | 5 | | 5 | 46·7 | 3 | 28 | 2 | |
| | 7 | | 9 | 32·3 | 2 | 55 | 29 | 13·3 |
| | 9 | | 13 | 16·9 | 2 | 22 | 45 | |
| | 11 | | 17 | 0·5 | 1 | 49 | 52 | 13·3 |
| | 13 | | 20 | 43·1 | 1 | 16 | 48 | |
| | 15 | | 24 | 24·9 | 0 | 43 | 35 | 13·2 |
| | 17 | | 28 | 5·8 | −0 | 10 | 11 | |
| | 19 | | 31 | 45·8 | +0 | 23 | 22 | 13·2 |

| | 29 | | 49 | 53·3 | 3 | 13 | 22 | |
| | 31 | 23 | 53 | 28·4 | +3 | 47 | 48 | 13·0 |

RELATION BETWEEN SOLAR ACTIVITY AND EARTH'S MOTION.—In the *Astronomische Nachrichten* (Bd. 152, No. 3635), Mr. W. G. Thackeray criticises the recent paper by Dr. J. Halm (*Astr. Nach.* Bd. 151, No. 3619, NATURE, March 8, p. 445), deducing certain relations between the sun-spot cycle, the changes in the obliquity of the ecliptic and the variations of the terrestrial latitude. Mr. Thackeray states first, that continuous observations of sun spots have only been made since 1825, so that the sixty years period lacks sufficient evidence; secondly, that Dr. Halm has ignored some of the systematic errors of observation, particularly those depending on the corrections for temperature in the transit circle reductions, although in some cases their amount affects the value of the obliquity by as great a quantity as the whole amplitude of Chandler's long period inequality of latitude variation. The paper includes a table showing the annual corrections to Leverrier's obliquity from 1836–1896, with corresponding yearly means of Wolf's spot numbers. These differ from the values adopted by Dr. Halm, and the resulting plotted curves show little or no resemblance.

DETERMINATION OF SOLAR PARALLAX FROM OPPOSITION OF EROS.—In the *Astronomical Journal* (No. 480, vol. xx. pp. 189–191), Prof. S. Newcomb directs attention to the favourable opportunity for determining the Solar Parallax which will be afforded by the comimg opposition of the minor planet Eros, in December 1900, the conditions being conducive to more accurate direct measurements than have ever before been presented. As another such favourable opportunity will not occur for more than thirty years, several suggestions are made for determining the best combination of observations.

The period during which determinations may be made is remarkably long, as during the five months from 1900 October 15 to 1901 March 15, the distance of the planet will be less than 0·50 astronomical unit.

The high degree of precision attainable in late years by photography indicates this as the best method, an additional point in favour of this plan being that photographic telescopes are already in use at various stations, and need only devoting to this work. In arranging the programme of observations three objects should be kept in view:—

First, the station and hours of exposure should be so chosen as to secure the maximum of parallactic angles.

Secondly, endeavour should be made to secure simultaneous exposures at different stations, in order to lessen the uncertainties arising from differences of scale, changes in relative position of planet among stars, and in the reduction of the position of the planet from hour to hour. Series of independent determinations should also be made, each within an interval of twenty-four hours.

Thirdly, the relative displacement should, as nearly as possible, be in a direction at right angles to the motion of the planet among the stars.

Prof. Newcomb then describes four charts included in the paper, showing projections of the earth as seen from Eros at the Epochs (1) middle of October to end of November; (2) about December 16; (3) about January 10; (4) about February 1. On these are marked the sunset and sunrise lines, and parallels of latitude corresponding to the principal observatories: Helsingfors, Pulkowa, 60° lat.; Greenwich, Paris, Potsdam, &c., 50° lat.; Jamaica, Madras, 15° lat.; Arequipa, −15° lat.; Cape of Good Hope, −35° lat. On these projections the direction of the planet's motion for different dates is indicated, so that observers may find by inspection the relative importance of observations at various stations and at various times of night.

Respecting the degree of precision it may be possible to attain in the final result, it is noticeable that the course of the planet throughout the entire period will lie along the borders of the Milky Way, ensuring more and nearer comparison-stars than would otherwise be available. An element of uncertainty is the probable error of measurement from the plates. From a consideration of Kapteyn's investigation of the Helsingfors parallax plates, and those at Potsdam, it is likely that the probable error of the solar parallax from a pair of simultaneous plates at Arequipa and Helsingfors would be ±0″·02, and even this might be reduced were it not for the uncertainty arising from the motion of the planet.

## WORKING SILICA IN THE OXY-GAS BLOWPIPE FLAME.

THE plastic state of silica, and the elasticity of fine threads of vitreous silica, were first observed by M. Gaudin (*Comptes rendus*, viii. 678, 711) in 1839; but his observations seem to have attracted but little attention, and the valuable qualities of "quartz threads" remained unutilised till they were independently rediscovered and applied by Prof. C. V. Boys in 1887.

Similarly, M. A. Gautier succeeded, in 1869, in making very narrow tubes of silica, and showed such tubes in Paris in the year 1878, but he failed to make further progress, even with the aid of M. Moissan's electric furnace (*Comptes rendus*, cxxx. 816, March 26), and his early work was so completely forgotten, both in France and England, that the latest French worker on the subject, M. A. Dufour, was evidently unaware of its existence a few weeks ago (*Comptes rendus*, cxxx. 775, March 19).

But though it thus appears that Prof. Boys was not, as has been supposed, actually the first physicist to draw silica into threads, or work it into fine tubes, there can be no doubt but that his observations, methods of working and experiments have formed the basis of all that has been done since the publication of his first paper in 1887.

In June 1899, one of the authors of this article exhibited (in conjunction with W. T. Evans), at the Royal Society's Soirée, a tube of vitreous silica, about 12 cm. in length and 1 cm. in diameter, and at the same time showed the process by which it had been made. Since that date we, the present writers, have made a good deal of further progress. We have succeeded in making longer tubes of various thicknesses, and in joining such tubes both end to end and at right angles. On February 22, we filled and sealed an ungraduated mercury thermometer made entirely of vitreous silica[1]; and what is equally important, we have entirely overcome the difficulty caused by the great tendency of quartz to splinter when suddenly thrust into the oxy-gas flame. We therefore now publish a short account of our methods in the hope that they may enable others to take advantage of the new material without undertaking a tedious preliminary investigation into its properties and the methods of working it. We may perhaps be permitted to add that we have already commenced experiments intended to test the suitability of silica for use in mercury and air thermometers, especially in regard to the fixity, or otherwise of their zero points, that M. A. Dufour is engaged on similar work, especially in relation to high temperature thermometers, and that we are also studying the fitness of silica apparatus for researches on the properties of pure gases.[2]

*To prepare Non-splintering Silica.*—The best form of silica for use before the blowpipe is rock crystal. This may be obtained in the form of chippings, or in masses which have proved unsuitable for optical work. We have experimented with the lighter particles of Kieselguhr, after well washing them with strong hydrochloric acid, and also with well-washed precipitated silica; but, though these can be worked before the blowpipe without much difficulty, they have not proved satisfactory in our hands, as they yield an opaque product which is only suitable for a few purposes.

---

[1] NATURE, April 5, p. 540.

[2] This will obviously involve a careful investigation into its power of condensing gases and vapours.

In order to prepare non-splintering silica from native masses of rock crystal, the latter must be heated in a Bunsen flame, unless they are already perfectly clean, until the outer impure layers can be removed easily by a blow from an iron pestle or hammer. The clean masses of silica must then be heated in a vessel containing boiling water for some time, and dropped whilst hot into clean cold water. This treatment will cause the masses to crack to such an extent that they may easily be broken into fragments of convenient dimensions by sharp blows from a clean hammer. When the material has thus been broken up, the fragments must be examined one by one, and all those which contain foreign matter must be rejected. Finally, the selected fragments must be heated to a yellow-red heat in a platinum dish, and then quickly thrown into deep cylinders containing cold distilled water. After the quartz has been treated in this manner twice, it will be found to be semi-opaque and very much like a white enamel in appearance. It may now be brought safely into the oxy-gas flame, or be pressed suddenly against masses of white-hot plastic silica without any preliminary heating, such as is necessary in the case of the natural quartz. These processes do not occupy much time, and the use of the prepared material saves a great deal of time and trouble at the subsequent stages. We have tried unprepared opal and natural cloudy quartz, but both these splinter badly.

*The Blowpipe.*—We have worked silica both in the flame of an ordinary "blow through" jet, and in the flame of a good "mixed gas" burner. We find the latter gives by far the more satisfactory results. The large "blow through" burners, such as may be used for welding and melting iron, or for melting platinum, do not give satisfactory results, from an economical point of view, with silica.

*Some necessary precautions.*—In working silica it is necessary to use very dark glasses to protect the eyes. The darkest glasses usually supplied by spectacle makers are not, in our experience, satisfactory. We use spectacles made specially from glass so strongly darkened, that it is difficult at first to work with them at all. We lay some stress on this matter, as we are satisfied that want of care in selecting the spectacles would be likely to result in injury to the sight of any one who should work silica before the blowpipe frequently, and for long spells.

*Relative difficulty of working Glass and Silica.*—The fashioning of apparatus from silica before the blowpipe is expensive, for the consumption of oxygen is large, and it demands some patience to build up large pieces of apparatus from shapeless masses of quartz. But owing to the remarkable fact that properly prepared silica, and also silica rendered vitreous by fusion, may be plunged directly into the hottest part of the oxy-gas flame, and afterwards be suddenly cooled, and reheated and recooled, apparently as frequently as one pleases, without any risk of its cracking, it is really very much easier to manipulate silica than any variety of glass. The most careless and most inexperienced worker runs no risk of breaking his apparatus through want of skill in managing the flame, or through the exigencies of his affairs compelling him to put aside half-finished work. It is important, however, to apply the flame to the opaque prepared silica, in the first instance, in such a way as to avoid the forming of air bubbles. Our practice is to heat first the lowest surface of each fresh mass of silica, and to take care that fusion proceeds regularly from below upwards. If this be done, a perfectly clear glass-like product is obtained.

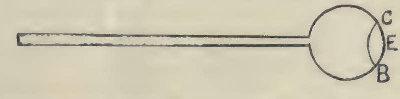
Silica is very liable to exhibit a phenomenon resembling devitrification, especially at the earlier stages before the traces of sodium and lithium, which seem to be present in most quartz, have been expelled. In order to avoid permanent injury to the finished work from this cause, care must be taken to employ a quiet flame. If this be done, any devitrification that may appear will be removed easily by reheating the disfigured surfaces.

*To make Silica Tubes.*— Before one commences to construct apparatus of silica it is well to prepare a stock of the vitreous material in the form of rods about 1 mm. in diameter. These are made by holding a small lump of non-splintering silica in the flame, by means of forceps with platinum tips, so as to melt one corner of the mass, pressing a second fragment of the material against the heated spot till the two adhere, heating the second portion from below upwards until it assumes a clear vitreous appearance, then adding a third fragment of silica to the second, a fourth to the third, and so on, until an irregular rod has been formed. Finally, this irregular rod must be reheated in small sections at a time, and drawn out to the desired extent. These rods are easily made by any one; a capable laboratory boy will produce about a score of rods 20 cm. long in an hour, after a few days' practice at the work; but his consumption of oxygen must be watched closely. The platinum tongs do not suffer much if one works in the manner described, for after the first start off they are only used to press *cold* fragments of silica against the fused ends of the growing rods. Our forceps have been used by four beginners, and are quite unharmed after several years.

When a supply of the rods of vitreous silica has been prepared, bind a few of them, at their ends, with fine platinum wire round a rod of platinum 1 to 1·5 mm. in diameter; heat the silica cautiously till the rods adhere to one another, and then withdraw the platinum core. If the tube is not perfect, add bits of silica at the defective places and reheat them. Close one end of the rough tube thus produced and blow a small bulb upon the closed end, proceeding in the manner employed for producing glass bulbs. Heat the bottom of the bulb, attach a rod of silica to it, reheat the whole bulb and then draw it out into a tube. Blow a fresh bulb at one end of the fine tube thus made, and draw this out in its turn until the tube is six or seven cm. in length. By the time this is accomplished the worker will have discovered that the hottest spot in his oxy-gas flame is just inside the tip of the inner cone, but not too near the orifice of the jet; and after this, if he can perform the simpler operations of glass working, he will, with a few weeks' practice, find it easy to make larger apparatus by following the simple instructions given below.

The chief difficulty met with when one wishes to make large bulbs, tubes, &c., is due to the fact that the only thoroughly satisfactory burners give comparatively small flames, and that it is only the hottest parts of these flames that give the desired results. There is no doubt, however, that suitable combinations of small burners could be contrived if they should be demanded, for the production of apparatus of really considerable dimensions.

In order to convert a small bulb of silica into a large tube, proceed as follows:—Heat one end of a fine rod of vitreous silica, and when it is in the plastic state apply it to the bulb at the point C. Then soften the adjacent parts of the rod and allow them to fall upon the bulb so as to form a ring C B, attached to the bulb. Heat the end of the bulb and C B till the silica softens, then blow out the end in the usual manner. If this process is repeated the bulb will first become ovate and then form a short tube which can be lengthened, practically speaking, indefinitely. Tubes of 1·5 cm. diameter and of considerable length are easily made in this way by a patient person. It does not answer to add lumps of silica at E and then to blow them out; we had no success in working silica till we abandoned that method. The sides of a tube formed in that way are too thin, and blow-holes constantly form in them. The tubes are easily thickened, when necessary, by adding rings of silica, reheating these, and blowing them to spread the material as one would do when working glass. It is best to blow through a chamber containing potash. If this is connected to the end of the silica tube by india-rubber "valve" tube, one is able to move the silica tube with sufficient freedom. If a large tube is being made, it is best to blow out the softened material whilst it is still in the hottest part of the flame, but smaller objects may be transferred to the less hot parts of the flame with advantage at the moment of blowing. When a comparatively large object must be uniformly heated, it is convenient to place a sheet of silica in front of the flame a little beyond the object to be heated, in order that it may throw back the flames upon those parts of the material which are turned away from the chief source of heat. A suitable plate of silica is easily made by sticking together small, rounded masses of vitrified quartz.



We find that it is not difficult to produce tubes of various thicknesses and various internal diameters by heating and collapsing thin tubes made as described above, and that fine capillaries, "thick millimetre tubes," and tubes of two or three millimetres bore, of moderate thickness, can be produced in this way. Thermometer stems are best made by adding rings of silica to small bulbs, thickening them in the flame till their cavities are very small, and then quickly drawing them out whilst soft. Finally, we may add that tubes of silica can as readily be sealed to one another as tubes of glass, and that T-pieces and side tubes generally may be formed by fixing rings of silica in the positions to be occupied by the side tubes and extending them by blowing as already described, or by attaching tubes of suitable dimensions, previously prepared, to short side tubes blown as just described. It is therefore possible to construct such apparatus as Geissler tubes, small distilling tubes, and thermometers with stems of the German type, &c. We feel sure that small flasks could easily be made also by means of suitable combinations of several oxy-gas burners, though doubtless they would be rather expensive.

Finally, solid rods of silica five or six millimetres in diameter can be made by putting together small masses of prepared silica, or better by pressing together in the flame the softened ends of the fine rods already described.

*Notes on some Properties of Vitreous Silica.*[1]—A good many of the properties of silica have already been described by Prof. Boys, but a knowledge of the following, some of which are, we think, now described for the first time, will be found useful:—

(1) Vitreous silica is a very poor conductor of heat; hence it is possible to hold a thick rod of silica very close to a strongly ignited zone.

(2) Our colleague, the Rev. H. Pentecost, finds that vitreous silica is less hard than chalcedony, but harder than felspar. Its surface appears to be about equally hard after it has been heated as strongly as possible and cooled suddenly, and after it has been heated and cooled in the air. Tubes of silica may be readily cut by means of a cutting diamond, and also with a good file of hardened steel.

(3) It has already been stated that cold vitreous silica can be plunged safely into the hottest part of an oxy-gas flame, and that the heating and cooling process can be repeated with impunity. Hot vitreous silica bears sudden cooling equally well. We have repeatedly plunged thick rods and large tubes of silica, heated till plastic, into cold water and even into fusible metal below 100°, without any injury to the material, for when afterwards cut with a diamond it did not fly.[2]

On the other hand, threads of silica become rotten when heated to the highest temperature of an ordinary blowpipe.[3] Large objects seem to be affected to a much less degree; and we suspect that this phenomenon may be due to surface devitrification. When silica is in this friable state it can be re-annealed by again softening it in the oxy-gas flame. According to Gaudin, wires of silica heated to a suitable temperature ("rouge-blanc") acquire great cohesion and become very elastic.

We have not yet succeeded in fixing platinum electrodes securely into silica tubes. But we have reason to hope that this may be found to be practicable by the use of kaolin, or some other natural silicate. Meanwhile, it seems possible that they might be soldered into the silica if necessary (see "Laboratory Arts," by R. Threlfall).

We may add that, according to M. Gaudin, emerald gives threads which are even more tenacious than those of silica.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The following is the Speech delivered, on April 26, by the Public Orator (Dr. Sandys) in presenting Mr. CHARLES HOSE for the degree of Doctor in Science, *honoris causa*.

Insulam Borneonem orbis terrarum inter insulas omnes prope maximam esse constat. Insulae autem illius insulis nostris fere duplo maioris in parte septentrionali patet regio quae unum e Britannis regem suum esse gloriatur. In eadem vero regione provincia quaedam, fluviorum ingentium infra confluentes, abhinc annos decem alumno nostro tradita est, qui barbarorum animos bellicosos pacis ad foedera vocavit, et armorum certamina saeva certaminis nautici in ludum mutavit. Idem non modo in foedere inter barbaros sanciendo victimarum caesarum haruspex sollertissimus, sed etiam avium in silvis volantium augur et auspex admirabilis exstitit. Ergo alumni nostri auspiciis et Helvetiae et Bataviae et Germaniae et Galliae et Britanniae musea avium et animalium exemplis eximiis aucta et suppleta sunt, et insulae ipsius zoologia, anthropologia, geographia, novo lumine illustratae. Talia propter merita alumnus noster non modo inter nosmet ipsos a regia geographiae societate praemio singulari donatus est, sed etiam inter Europae gentes tum aliis honoribus ornatus est, tum praesertim inter Germanos falconis albi eques iure optimo nominatus est. Nostra denique zoologiae, anatomiae, archaeologiae musea iam plus quam decimum per annum alumni nostri liberalitatem loquuntur. Ergo nos quoque insulae tantae non modo avium et animalium venatorem assiduum, sed etiam montium et fluminum exploratorem intrepidum, ob scientiarum fines etiam imperii Britannici prope terminos feliciter propagatos, laurea nostra hodie libenter coronamus.

Duco ad vos museorum nostrorum patronum liberalissimum, exploratorum nostrorum hospitem benignissimum, CAROLUM HOSE.

The General Board propose the establishment of a lectureship in ethnology, to which Dr. Haddon may be appointed; and a lectureship in bacteriology and preventive medicine for Dr. Nuttall. Both have unofficially given valuable instruction in their respective subjects, and the recognition now suggested will probably be readily accorded by the University. New lectureships in experimental physics and in agricultural chemistry are also proposed.

The Board of Agricultural Studies, at the close of their first financial year, make a highly satisfactory report. Their income is sufficient for the provision of a complete course of instruction, which has now been organised under the direction of Prof. Somerville. They now ask the University to establish a special examination in agricultural science (botany, chemistry, physics and geology) for the ordinary B.A. degree.

---

THE history of the University of London, from the time of Sir Thomas Gresham's bequest, in 1575, of his house and garden in Bishopsgate, for the purposes of education, down to the completion of the work of the commissioners appointed under the University of London Act, 1898, is traced in an interesting article in the current number of the *Quarterly Review*. The large part the University has taken in the renascence of natural science, which will hereafter be regarded as the main characteristic of intellectual progress in the nineteenth century, is pointed out, as well as the fact that London degrees in science were the first conferred by British universities.

WE learn from *Science* that the University of Chicago has secured the 2,000,000 dollars needed to meet the requirements of Mr. Rockefeller's gift of an equal amount. At the recent convocation of the University, President Harper gave some details in regard to the gifts received since January 1st. They have come from more than 200 different persons, and 90 per cent. of them were unsolicited. The largest items appear to be the Gurley palæontological collection, 30,000 dollars from Mrs. Delia Gallup, and, given anonymously, 60,000 dollars for a commons, 50,000 dollars and 25,000 dollars for a students' club-house, 20,000 dollars towards a women's hall, and 30,000 dollars with specific use to be designated later. President Harper stated that the total assets of the University are now not far from 11,000,000 dollars.

THE Technical Education Board of the London County Council will proceed shortly to award five senior county scholarships, each of the value of 60*l*. a year for three years, with free tuition fees up to 30*l*. a year. These scholarships are intended to assist young men and women to pursue a course at some University or at a technical college of University rank. Some of the scholars who have been elected in previous years are holding their scholarships at Oxford and Cambridge, others are studying at technical colleges in different parts of England, while others are pursuing courses of study on the Continent. The scholarships are open only to candidates who are under twenty-two years of age, and whose parents are in receipt of not more than 400*l*. a year. In addition to the senior scholarships, the board has in past years made a certain number of grants of smaller value to assist students in pursuing advanced education, and the board has at its disposal a certain number of free places at University College, London, King's College, London, and Bedford College, London. The scholarships and grants are awarded, not on the result of a set examination, but on the consideration of the past achievements and promise of the candidates. Application forms may be obtained from the secretary of the Technical Education Board, 116, St. Martin's Place, W.C., to whom they should be returned not later than May 14. The board is also offering scholarships for the encouragement of horticulture and gardening. Two of these, tenable at the Swanley Horticultural College, Kent, give free board and tuition for two years, and may be reckoned as of the value of 60*l.* a year. They are open to candidates between the ages of sixteen and twenty, and one will be awarded to a young man and the other to a young woman as the result of a competitive examination. No candidate is eligible whose parents are in receipt of more than 400*l.* a year.

---

[1] See also Gaudin, *loc. cit.*

[2] Gaudin obtained similar results with drops of *liquid* silica.

[3] Gaudin observed a similar phenomenon in the case of fine threads, and so also, we believe, did Boys.

---

## *SOCIETIES AND ACADEMIES.*

### LONDON.

**Physical Society.**—Ordinary meeting held by the invitation of Sir Norman Lockyer, F.R.S., in the Solar Physics Observatory, South Kensington, on April 27.—Mr. T. H. Blakesley, Vice-President, in the chair.—Sir Norman Lockyer gave a short account of the physical problems now being investigated at the Solar Physics Observatory, and their astronomical applications. The chief work carried on at the observatory is the comparison of stellar spectra with spectra obtained from lights emitted by laboratory sources. The light from a star (or the sun) and from an arc (or a spark) are focussed alternately upon the slit of a spectroscope, and the two spectra are photographed side by side upon the same plate. The number of lines in the arc spectrum depends upon which part of the arc is focussed on the slit. The image of the centre is rich in lines, the image of the edge gives a few single lines. Changes in spectra are also dealt with. The thickening and thinning of lines depends upon several things. In the first place, it depends upon the density of the substance, and thus the hydrogen lines in the spectrum of Sirius are much broader than those in $\alpha$ Cygni, the hydrogen being denser in the former star. Changes may also be produced by variations in quantity. A reduction in the quantity of a substance generally simplifies its spectrum, the longest line disappearing last. The motion of a luminous body to or from the spectroscope alters the wave-length of the light emitted and produces a shift in the lines of the spectrum. The amount of deviation is a measure of the velocity in the line of sight. In the case of Nova Aurigæ, we have dark and bright lines of the same substance side by side. This shows that there are two bodies involved, moving with different velocities, the one giving a radiation and the other an absorption spectrum. Another change in the lines depends upon temperature. In general an increase in temperature produces a greater number of lines, a notable exception being sodium, which gives its full number of lines at the temperature of an ordinary Bunsen flame. The spectra of metals obtained from the arc, and by sparking, are often quite different. Those lines which make their appearance, or are intensified in passing from the arc to the higher temperature of the spark, are known as enhanced lines. The comparison of stellar spectra with laboratory spectra is often easy. For instance, the presence of iron in the sun and hydrogen in Sirius is easily seen. Several lines in the spectrum of Bellatrix have been shown to be due to helium, the position of the lines being exactly the same as those due to the gases from clevite. In many cases it is possible to build up the spectrum of a star from the spectra of its constituents taken at the proper temperatures. For instance, the spectrum of $\gamma$ Orionis can be closely imitated by means of oxygen, nitrogen, and carbon together with the well-marked lines of hydrogen and helium. We can roughly estimate by the character of the spectra of stars, the temperatures of those stars, and thus arrive at a stellar thermometry. Starting with a hot star like Bellatrix, and passing through $\beta$ Persei, $\gamma$ Lyræ, Sirius, Castor, Procyon to Arcturus, a cold star, we have a gradual change in the character of the lines which appear in the spectrum of any constituent. The widening of the lines in the case of spectra of sun spots enables us to trace changes in temperature of the sun, and we can compare these temperature changes with a variety of terrestrial phenomena, such as variation in latitude. The extraordinary number of lines exhibited by many metals suggests that what we are accustomed to call chemical elements are really complex bodies which are made up of simpler ones. Attempts have been made to build up the spectra of metals by superimposing simple sets of lines upon one another. In many cases a great number of series would be required to represent things completely. In the case of hydrogen it would be necessary to have at least twenty-seven series to give the structure spectrum only. Taking the atomic weight of hydrogen as unity, the atomic weight of the little masses which might give rise to any one of these series would be about ·0019. This is of the order of magnitude of the small bodies, of which the existence has been suggested by Prof. J. J. Thomson from his work on ions.

### PARIS.

**Academy of Sciences.**—M. Maurice Lévy in the chair.—The President announced to the Academy the death of M. Alphonse Milne-Edwards, and gave an account of his work.—On linear partial differential equations of the second order, and on the generalisation of the problem of Dirichlet, by M. Émile Picard.—On the heats of combustion and formation of some iodine compounds, by M. Berthelot. A redetermination of the heats of combustion of fourteen typical iodine derivatives. In spite of preconceived notions to the contrary derived from the incomplete combustion of such compounds as iodoform in air, no difficulty was experienced in completely burning any of the substances in the calorimetric bomb.—On rifling in cannon, by M. Vallier. A discussion on the best form of curve for the rifling of cannon, and an extension of the work of M. Zaboudski upon the same subject.—On the upright trunks, stems and roots of Sigillaria, by M. Grand'Eury. A study of the Sigillaria existing in a quarry in the neighbourhood of St. Étienne. From the fact that the stems (*Syringodendron*) found in a vertical position are not distributed at random, but are usually found in groups near each other forming well marked colonies, and from other characters of their growth, the author concludes that the hypothesis of R. P. Schmitt that they have been transported by water and deposited in the position found, is untenable. The view of Dawson that they have grown upon unsubmerged soil is also held to be untenable, all the facts noted by the author pointing to the Sigillaria have grown in the place in which they are found in marshy soil; under water varying from 1 metre to 7 or 8 metres in exceptional cases.—Reply to a reclamation of priority of M. Curie, by M. Gustave le Bon.—Reply by M. Th. Tommasina to a reclamation of priority, by MM. Ducretet and Popof.—Note by M. L. M. Bullier replying to M. Geelmuyden on a question of priority.—On the complementary terms in the criterium of Tisserand, by M. Gruey.—On differential equations of any order whatever with fixed critical points, by M. Paul Painlevé.—On the generalisation of analytical prolongation, by M. Émile Borel.—The theoretical cycle of gas engines, by M. A. Witz. A discussion of the remarks and criticism of M. Marchis.—On the dielectric constant and the dispersion of ice for electromagnetic radiations, by M. C. Gutton. The value of the refractive index for electromagnetic waves was found to vary with the wave-length from 1·76 for a wave-length of 14 cm. to 1·50 for 2088 cm., ice thus presenting normal dispersion for electromagnetic waves.—Two applications of Govi's camera lucida, by M. A. Lafay.—On the maximum sensitiveness practically employed in coherers for wireless telegraphy, by MM. A. Blondel and G. Dobkévitch. The increase of sensibility observed by M. Tissot to occur when the coherer is placed in a magnetic field, is ascribed by the authors to purely mechanical causes, the increase of contact between the powder and the electrodes produced by their mutual attraction.—On the radiations of radium, by M. E. Dorn. The author draws attention to the fact that he published a note on the deviation of the rays emitted by radio-active barium bromide in an electric field on March 11, independently of M. Becquerel.—On a new thermo-calorimeter, by M. G. Massol. Two improvements on Regnault's thermo-calorimeter are suggested, the replacement of alcohol by sulphuric acid, giving a large increase in the range of the instrument, and the use of a reservoir at the upper end of the instrument as in Walferdin's maximum thermometer by which the sensitiveness of the thermo-calorimeter is increased without undue lengthening of the stem. The instrument thus modified has been of especial service in the study of superfused liquids.—A new indicator in acidimetry, and its application to the estimation of boric acid, by M. Jules Wolff. The indicator proposed is a solution of ferric salicylate in sodium salicylate, which passes from violet to orange when the solutions become alkaline. Data are given showing the results obtainable with borates.—On the selenides and chloroselenides of lead, by M. Fonzes-Diacon.—Crystallised lead selenide, $PbSe$, is obtained by reduction of a selenate by hydrogen or by carbon, by the action of hydrogen selenide upon the vapours of lead chloride, and by the direct fusion in the electric furnace of precipitated lead selenide.—On the alkaline selenio-antimonites, by M. Pouget. Selenio-antimonites can be obtained of analogous composition to the sulpho-antimonites already known; mixed sulphur and selenium compounds, thioantimonites in which the sulphur is only partially replaced by selenium have also been prepared.—Micro-chemical researches on yttrium, erbium and didymium, by MM. M. E. Pozzi-Escot and H. C. Couquet.—Mechanism of the senility and death of nerve cells, by M. G. Marinesco. As the result of a study of nerve cells from the brain and spinal column of individuals of ages ranging from 60 to 110, it was found that the modifications constituting the old age of the nerve cell do not only consist of the diminution, more or less marked, of this body, but include other more interesting changes, some of which, tangible to the microscope, are described.—Heteroplastism, by M. Nicolas-Alberto Barbieri.—A determination of the conditions under which tissue from one mammal can be grafted on to another, to replace similar tissue. The results of experiments are given on the grafting of muscular, vascular, and nervous tissue.

## DIARY OF SOCIETIES.

### *THURSDAY*, May 3.

Royal Institution, at 3.—A Century of Chemistry in the Royal Institution: Prof. J. Dewar, F.R.S.

Linnean Society, at 8.—Note on the Movements in Fishes: Prof. R. J. Anderson.—On New Species of *Halimeda*, from Funafuti: Miss E. S. Barton.—On West Indian Fungi: Miss A. L. Smith.

Chemical Society, at 8.—Brazilin, Part IV.: A. W. Gilbody, W. H. Perkin, jun., and J. Yates.—Hæmatoxylin, Part V.: W. H. Perkin, jun., and J. Yates—The Substituted Nitrogen Chlorides and Bromides derived from *o*- and *p*-acet-toluide and their Relation to the Substitution of Halogens in Toluides and Toluidines: F. D. Chattaway and K. R. P. Orton.

Röntgen Society, at 8.—Demonstration and Exhibition of New Methods and Results.

Institution of Electrical Engineers, at 8.—If the discussion on Prof. Forbes's Paper, read on April 26, is concluded, the following Paper will be read:—The Calculations of Distributing Systems of Electric Traction under British Conditions: H. M. Sayers.

### *FRIDAY*, May 4.

Royal Institution, at 9—Pottery and Plumbism: Prof. T. E. Thorpe, F.R.S.

Geologists' Association, at 8.—Some Features of the Recent Geology of Western Norway: Horace W. Monckton.

Cold Storage and Ice Association (Examination Hall, Victoria Embankment), at 11.30.—Recent Researches in Refrigeration: G. Halliday.—Insulation and Insulators: W. D. A. Bost.——At 3.—Electric Lighting of Cold Stores: W. B. Esson.—The Design and Construction of Buildings for Ice Factories and Cold Storage: P. Gaskell.

### *SATURDAY*, May 5.

Royal Institution, at 3.—Egypt in the Middle Ages: Prof. Stanley Lane-Poole.

### *MONDAY*, May 7.

Society of Arts, at 8.—The Incandescent Gas Mantle and its Use: Prof. Vivian B. Lewes.

Society of Chemical Industry, at 8.—The Production of Nitrate of Soda in Chili: Dr. W. Newton.

### *TUESDAY*, May 8.

Royal Institution, at 3.—A Corner of Sussex: Dr. H. R. Mill.

Society of Arts, at 8.—Art Metal Work: Nelson Dawson.

Zoological Society, at 8.30.—A List of the Batrachians and Reptiles of the Gaboon (French Congo), with Descriptions of New Genera and Species: G. A. Boulenger, F.R.S.—On the Birds of Hainan: W. R. Ogilvie Grant.—On the Rhopalocera collected by the late Mr. John Whitehead in the Interior of the Island of Hainan: Philip Crowley.

Royal Photographic Society, at 8.—The Effect of Colour on Gradation: Chapman Jones.

### *WEDNESDAY*, May 9.

Society of Arts, at 8.—Improvement of our Roads: A. Moresby White.

Geological Society, at 8.—The Pliocene Deposits of the East of England. Part II. The Crag of Essex (Waltonian) and its Relation to that of Norfolk and Suffolk: F. W. Harmer. With a Report on the Inorganic Constituents of the Crag by Joseph Lomas.—The Salt Lake of Larnaca (Cyprus): C. V. Bellamy.

Iron and Steel Institute, at 10.30.—General Meeting.—On Blowing-Engines driven by Crude Blast-Furnace Gas: Adolphe Greiner.—The Solution Theory of Iron: Baron H. von Jüptner.—The Use of Fluid Metal in the Open-Hearth Furnace: James Riley.—Iron and Phosphorus: J. E. Stead.—The Continuous Working of the Open-Hearth Furnace: Benjamin Talbot.

### *THURSDAY*, May 10.

Royal Society, at 4.30.—*Probable Papers*: On the Diffusion of Gold in Solid Lead at the Ordinary Temperature: Sir W. Roberts-Austen, F.R.S.—On Certain Properties of the Alloys of the Copper-Gold Series: Sir W. Roberts-Austen, F.R.S., and Dr. T. K. Rose.—Experiments on Supposed Vascular and Visceral Factors in the Genesis of Emotion: Prof. Sherrington, F.R.S.—On the Brightness of the Corona of April 16, 1893. Preliminary Note: Prof. H. H. Turner, F.R.S.

Royal Institution, at 3.—A Century of Chemistry in the Royal Institution: Prof. J. Dewar, F.R.S.

Mathematical Society, at 5.30.—Special Meeting.—The Differential Equation whose solution is the Ratio of Two Solutions of a Linear Differential Equation: M. W. J. Fry.—A Congruence Theorem relating to Eulerian Numbers and other Coefficients: Dr. Glaisher, F.R.S.

Institution of Electrical Engineers, at 8.—A Frictionless Motor Meter: S. Evershed.

Iron and Steel Institute, at 10.30.—Ingots for Gun Tubes and Propeller Shafts: F. J. R. Carrulla.—The Manufacture and Application of Water-Gas: Carl Dellwik.—The Equalisation of the Temperature of Hot Blast: Lawrence Gjers and Joseph H. Harrison.—The Manganese Ores of Brazil: H. Kilburn Scott.—The Utilisation of Blast-furnace Slag: Ritter Cecil von Schwarz (Liége).

### *FRIDAY*, May 11.

Royal Institution, at 9.—Shakespeare and True Patriotism: Sidney Lee.

Royal Astronomical Society, at 8.

### *SATURDAY*, May 12.

Royal Institution, at 3.—South Africa; Past and Future: Dr. Alfred P. Hillier.

## MECHANISM, IDEA, OR—NATURE?

*Naturalism and Agnosticism.* By James Ward, Sc.D. 2 vols. Pp. xviii + 302 and xiii + 291. (London: A. and C. Black, 1899.)

THE distinguished writer of the well-known article on psychology in the "Encyclopædia Britannica" could not but be sure of a welcome for any contribution towards the establishment of a world-formula that he found it in him to offer. Prof. James Ward displays analytical power of quite first-rate quality, even when he uses it perversely. He has an insight more than common into the bearings of scientific methods and naturalistic speculations, even when he is disputing their competency or restricting their range. If his lucidity is that of the successful teacher, his earnestness and his often eloquence mark the great one. Finally, in meeting the apostles of naturalism within the jurisdiction of their own categories, and without the mystification of an alien esotericism, he has set an example of hopeful augury. "Naturalism and Agnosticism" is for these reasons one of the books that must count.

On the other hand, while future attempts at construction cannot neglect the reasonings of this very considerable work, Prof. Ward's is not a mind "to nestle in." His attack upon Naturalism with Agnosticism must, we venture to think, be held to have failed, his conclusion to Spiritualistic Monism to be illicit.

Prof. Ward's book embodies his Gifford lectures, in defence of theism, delivered at Aberdeen in the years 1896 to 1898. As they "take it for granted that till an idealistic (*i.e.* spiritualistic) view of the world can be sustained, any exposition of theism is but wasted labour," they are in effect a critique of Naturalism and Agnosticism singly and together, followed by a brief development of a Monism of Spirit, in whose interests they are assailed. Their "demurrer" to theistic inquiries is ruled out, because they themselves, it is claimed, have failed.

We may pass the question whether a Naturalism that dares to say that it sees no way of access to knowledge of a certain kind, "demurs" to theism in any manner in which "spiritualistic monism," with its implicit pantheism, does not, and consider rather the development of Dr. Ward's attack on Naturalism. He tries a fall with it in three fields—Mechanism, Evolution taken as the working of Mechanism, and Psychophysical Parallelism as the device by which the mechanical view disposes of the importunate facts of consciousness. It seems to follow that unless Naturalism must be identified with Mechanism our author's thesis fails.

As regards Mechanism, Dr. Ward disclaims any pretensions to specialism in physics, but he shows such intellectual communion with the studies that are the great glory of his university, that he fully sustains his right to be heard. His fundamental point is the abstractness and hypothetical character of modern physics. He shows how they pass from the perceptual and actual into what has been happily called "conceptual shorthand." He finds mathematical physics "idealistic" in their procedure—epistemologically, we presume, not ontologically—and he claims that they do not set before us "what verily is and happens." Matter, mass, energy—what are these? We seem driven to modify our ideas of them again and again, till we end either in Nihilism, with, for instance, Kirchhoff, or in some highly artificial formula, such as, *e.g.* the "hydrokinetic ideal" of Lord Kelvin. From the point of view of logic, the inverse methods of abstract physics are such that our ultimate principle will not necessarily be a *vera causa* in the sense of one who can say *hypotheses non fingo*. If, then, we accept it as ultimate reality, we are simply Neopythagoreans. Can we construct from it a cosmos of qualitative variety? much less an organic world.

Yet, starting from mechanism, such an attempt at edification has been made by Mr. Herbert Spencer. To him the sciences in their evolutionary gradation appear to offer a closed system, a polity, a synthesis which is philosophy. The absence of the two volumes essential for the bridging of the gap from inorganic to organic, and especially of that famous chapter in which, "were it written," the transition is actually made, puts Mr. Spencer's high claims out of court. But further, by playing off dissipation of energy against conservation, the doctrine of "First Principles" can be shown to be inadequate. And Mr. Spencer's demand for instability of the homogeneous at the start, instability of the heterogeneous at the finish, shows his construction to be arbitrary. To get evolution to the point of a working process, we need, says Dr. Ward, a teleology—"evolution with guidance," or plan, or purpose. And this to our author implies something incompatible with mechanism, mind in some transcendental sense, god. There is perhaps a lacuna in the inference, but so comes the god into the mechanism

But if mind is thus to be, at the very least, the predominant partner in the world-system—it is to be much more—Dr. Ward must get rid of Psychophysical Parallelism. Psychosis cannot be epiphenomenon, nor, to use Huxley's unfortunately loose phrase, a "collateral product." Nor can man—though this is not the same thing—be a conscious automaton. We cannot have any implication of "the impotence of mind to influence matter." We must admit "interaction," because "invariable concomitance and absolute causal independence are incompatible positions."

But if there is not only room for god, as Brahma so to speak, at the beginning, but also both room for and need of, as it were, Vishnu, throughout the working of the mechanism, to save it from nihilism, to supply "guidance" to the evolutionary process, to infuse new energy, or, as "the sorting demon of Maxwell," restore wasted energy, to account for life, to work as immanent sustaining force throughout, we need only to refute dualism in favour of a "duality of subject and object," and the way is clear for idealism.

But is this so? Is naturalism really refuted? Is neutral agnosticism illicit, or, in the alternative, so unstable, as to be necessarily materialist or mechanical in bias? Or has Dr. Ward haply shown that certain physicists, like certain idealists, have no right to their creed? Those, namely, who fail to take their symbols as formulæ, abstractions, averages, or to see that where explanatory, the range of their power of explanation is limited. Or has he perhaps overthrown much in the hasty constructions of Huxley and Mr. Spencer, made in the first flush of the reconnaissance in force of militant science, but left Naturalism the while untouched?

Dr. Ward's polemic against Mechanism is, we take it, justified with some qualifications, as against those who hold that the synthesis of naturalism is complete, and that the law of its continuity implies the resolution of all phenomenal realities into terms of the modern substitutes for matter in motion, conceived of as having no qualitative but only quantitative determinations. Again, the unnecessarily contemptuous criticism of Evolution as the working of mechanism is valid against Mr. Spencer's "First Principles." Mr. Spencer's mastership happily does not rest upon the soundness of the too early stereotyped foundation, nor on the claim that the edifice is complete to its coping-stone. Further, if "science" is at the standpoint of the materialism of Laplace, or even if it has taken the Huxley of the early sixties, with his undoubted materialist bias, as guide in all things, it will have to retrace the steps it has taken in its advance towards a creed. If it abstracts the known from the knower, and maintains that the act of abstraction makes no difference, it can be convicted of positing a phenomenal world *per se*. If, in the faith of continuity, it says that the inorganic, as it is conceived by mathematical physics, not only conditions but also constitutes the organic, in the sense that we must not, in order to explain the organic, look for anything in the inorganic other than those mathematical determinations of which alone abstract physics take account, then it is against that long patience which is the chief of discoverers, and is attempting an "anticipation" of experience. If it treats regulative as constitutive principles, and attributes agency to formulæ, it is guilty of what we had thought was specifically the idealist's fallacy. But must Naturalism do these things?

We might instance Dr. Hodgson's experientialism and Prof. Münsterberg's transformism among types of naturalism able to "let the galled jade wince." Surely, too, the specialist, finding in his own department, recognised as partial and abstract, the immanence of law, and learning that his colleagues in other departments find law there too, and so throughout, is justified in believing that out of nature—human nature, and specifically the nature of human thought included—the solution must come. Unable to find a mediating term between his "non-matter in motion" or what not, and psychic process, he accepts the "parallelism," with hypothetical connection as co-aspects or, since Prof. Ward, despite of Kant and Mr. Bradley, prefers the causal relation, co-effects of a unitary system. And if to the knowledge of this he sees no road from the human standpoint, wherein lies the illicitness of the union, always stigmatised by Dr. Ward as an evil *liaison*, between his positive treatment of his facts of science and his agnostic neutral attitude, without bias either materialist or spiritualist, towards the ultimate real?

Dr. Ward thinks, in terms of the quotation on his title-page, that law implies teleology, and that teleology implies spiritualistic monism. We do not see the steps by which he establishes this latter point. And he thinks neutral agnosticism unstable in the direction of one bias or other. We do not see why.

Surely in taking Naturalism "to designate the doctrine that separates Nature from God, subordinates Spirit to Matter, and sets up unchangeable law as supreme," Dr. Ward has imposed upon it three characters—the first an ambiguity, the second a mechanical bias which is not essential to it, the third its pride, or what it would repudiate, according to the meanings attached to the words "law" and "supreme." It is he who has conjured up what, by a curious slip, he calls "a novel Frankenstein."

We cannot accept Dr. Ward's criticism of psycho-physical parallelism. Mr. Stout, who also "carried Cambridge to Aberdeen," is to the point here. He treats it as the best mode of formulating the facts, but needing for explanation something beyond itself. That he finds this something in an idealist metaphysic makes his witness the more impartial. Prof. Ward hankers after "interaction," or at least "activity of mind." The first, in the form in which he demands it, involves him, to our thinking, in a dualism, which is not a duality of subject and object, and for which his own "refutation of dualism" is enough. The second is spiritualism, which, if monistic, precisely inverts material monism and makes man a conscious automaton from the other point of view.

We may note in this connection a sceptical argument of Dr. Ward's. In what seems to be a misapplication of the formula of "introjection," which he applies elsewhere with signal success, he insists that my *psychoses* are experience only for me, my *neuroses* experience only for the physiologist. The inference surely must be to solipsism or to nothing. Does Dr. Ward mean to deny the accompaniment of my psychical phantasmagoria with brain change?

The quality of Dr. Ward's idealism is perhaps to be doubted. Where does he get the "voluntary movement" which is essential to our perception of space? We are not quite sure that his "intellective synthesis" gives him a right to a world of "intersubjective intercourse" at all. It is, to use an illustration of his own, a case of genii each hermetically sealed in his bottle, but collectively at large. Or it is natural realism. Again, his mental "activity" is in collision with the teaching of Mr. Bradley.

Dr. Ward must have creative agency for thought if "nature is spirit" (though if this be so in a plain, straightforward sense, then why naturalism is wrong from the point of view of spirit is hard to see). But all thought that we know is accompanied with body, and does not create. Huxley "quite rightly refuses to convert invariable concomitance into necessary conjunction." If that is so, what becomes of Dr. Ward's formula as to parallelism and causal independence, apart from his fallacious use of it to establish interaction, when the "community" need not imply more than that they are aspects or, if Dr. Ward will have it so, co-effects of the same real?

Prof. Ward declines to allow analysis to be adequate unless you can find your way back to complete synthesis. Judged by this test, what becomes of Spiritualistic Monism? Indeed, the double edge of Dr. Ward's arguments is one of the marked characteristics of his book. What is good for "non-matter in motion" is good for Green's "relations without *relata*." What is good for Lord Kelvin's Plenum is good for Mr. Bradley's Reality. A dialectical process, which must take place in a time considered to be riddled with self-contradictions and *aufgehoben*, is analogous to the form of evolution that

Dr. Ward eviscerates. In truth, mechanism inverted is spiritualistic monism. The naturalism not yet fully formulated, which has allied itself provisionally and in no way illegitimately with neutral agnosticism, is happily neither materialism nor idealism. H. W. B.

## *THE EVOLUTION OF EUROPEAN PEOPLES.*

*The Races of Europe: a Sociological Study.* By William Z. Ripley, Ph.D. Pp. 624; and bibliography, pp. 160. 222 portrait types; 86 maps and diagrams, and other illustrations. (London: Kegan Paul, Trench, Trübner and Co., Ltd., 1900.)

IT has been reserved for an American anthropologist to give us the first comprehensive work on the races of Europe, a subject which is as fascinating as it is important.

The first two chapters of this comprehensive work deal with general questions, among others the problem of environment *versus* race in determining ethnic characters is touched upon, and the error of confusing community of language with identity of race is pointed out; nationality may often follow linguistic boundaries, but race bears no necessary relation to them.

As the main arguments in the book are derived from a consideration of three main sets of comparative data—the head-form, hair- and eye-colour, and stature—it was necessary to discuss their value, and in doing so the author has passed in brief review various races of man in all parts of the world. As the shape of the head, that is the length-breadth, or cephalic index, is not liable to be affected by environment as pigmentation appears to be, and stature certainly is, it takes the first rank as a criterion of race, the colour of the hair and eyes comes second, while stature is relegated to the third rank.

Dr. Ripley states as a proposition that is "fairly susceptible of proof":

"The European races, as a whole, show signs of a secondary or derived origin; certain characteristics, especially the texture of the hair, lead us to class them as intermediate between the extreme primary types of the Asiatic and the negro races respectively."

Surely the wavy-haired group of mankind has as much a claim to be considered primitive as are the frizzly- or the straight-haired groups. That certain characters are intermediate does not imply that a mixture has taken place. In some respects each of these three main groups of mankind is nearer to, and in others further from, the higher apes than the other two groups; the wavy character of the hair of the Europeans, for example, is probably an ancestral feature that has been retained by them and the other Cymotrichi.

The earliest and lowest strata of population in Europe were extremely long-headed, and the author regards the living Mediterranean race as most nearly representative of them. He considers it highly probable that the Teutonic race of Northern Europe is merely a variety of the primitive long-headed type of the Stone Age; both its distinctive blondness and its remarkable stature having been acquired in the relative isolation of Scandinavia, through the modifying influence of environment and artificial selection. It is certain that, after the partial occupation of Western Europe by a dolichocephalic type in the Stone Age, an invasion by a broad-headed race of decidedly Asiatic affinities took place. This intrusive element is represented to-day by the Alpine type of Central Europe.

It is the play of these three groups, Teutonic or Nordic, Alpine and Mediterranean, upon one another, together with the effect of environment, the potency of which varies locally, occasional isolation and sexual selection, which has resulted in the complexity of the ethnology of modern Europe.

Dr. Ripley deals with the various countries of Europe, and endeavours to unravel the anthropological history of each. It is a humiliating fact how often political or religious bias has crept into ethnological arguments; but our author approaches the subject with an unprejudiced mind, and looks at the problem from a broad point of view.

The most remarkable trait of the population of the British Isles is the uniformity of its head-form; the prevailing type is that of the long and narrow cranium, accompanied by an oval rather than broad or round face. The length-breadth indices all lie between 77 and 79, with the possible exception of the middle and western parts of Scotland, where they fall to 76. This index alone proves little in the present instance, and recourse must be made to other characters, such as hair-colour and stature.

These distinctly prove a dual element in the population, one of which is the persistent Neolithic stock, a branch of the Mediterranean race; the other is the northern race, composed of Saxon, Danish and Norwegian elements. Immigrants belonging to the Alpine race, not pure, but as a mixed people, overran all England and part of Scotland, bringing with them bronze implements, the art of pottery-making, and other cultural advantages; but their physical influence was transitory, for at the opening of the historic period the earlier types had considerably absorbed the new-comers, and the Teutonic invasion completed their submergence. Dr. Ripley, however, is scarcely correct in stating that the Alpine immigrant type never reached Ireland, as traces of them have been recorded (*cf. Proc. Roy. Irish Acad.* (3), iv. 1898, p. 570). The distribution of stature bears out a distinction between the Goidels and the Brythons; but the high stature found in South-west Scotland is anomalous, and requires further study.

It is impossible to deal with all the controversial problems in the book, but an author can generally be gauged by his treatment of critical cases, and of these it is no exaggeration to say that Dr. Ripley always takes a sane position. The origin of the Etruscans is a case in point. The different views of various authors are briefly stated, but the author inclines to Sergi's theory that the Etruscans were really compounded of two ethnic elements, one from the north bringing the Hallstatt civilisation of the Danube Valley; the other Mediterranean, both by race and culture. The sudden outburst of a notable civilisation being the result of the meeting of these two streams of human life, the author appears to have overlooked the probability of a similar history for early Greece.

A whole chapter is given to a discussion of the Basques, and Collignon's deductions are adopted. The French

Basques of to-day are more pure than the Spanish; but they originally came from Spain. Although the Basque face is extraordinarily narrow, the head is broad; but this is not due to a mixture with the Alpine race, as the Basque head is essentially dolichocephalic, the breadth occurring pretty far forwards near the temples. We have here, in fact, an example of a local modification (a sub-species of the Mediterranean stock) evolved by long-continued and complete isolation, in-and-in breeding primarily engendered by peculiarity of language, and perhaps intensified by artificial selection.

After having analysed the various European groups, Dr. Ripley devotes a couple of chapters to European origins and others to social problems, such as environment *versus* race, acclimatisation, and urban selection; in the latter he discusses the tendency to long-headedness, shortness of stature and brunetness that characterises most large towns.

Dr. Ripley has presented us with a very valuable and most interesting study of the origins and physical characteristics of various European peoples, which is as indispensable to students of history and sociology as it is to anthropologists. The clearness with which he states and illustrates his facts leaves nothing to be desired, and we offer him our congratulations on having coped so successfully with an intricate problem, and on having brought his laborious researches to such a satisfactory conclusion.

The book is handsomely "got up," and is sumptuously illustrated. There are 222 carefully-selected portrait types, and 86 maps and diagrams. The selection of the portraits could have been no easy task, and the construction of the distributional maps must have entailed an infinitude of labour. The volume concludes with a bibliography on the anthropology and ethnology of Europe, which is as appalling as it is invaluable.

A. C. Haddon.

## A REVISION OF CERTAIN CELL PROBLEMS.

*Histologische Beiträge, Heft VI.: Ueber Reduktionstheilung, Spindelbildung, Centrosomen und Cilienbildner im Pflazenreich.* Von E. Strasburger, o.ö. Professor an der Universität Bonn. Pp. xx + 224. Mit. vier litho. Tafeln. (Jena: Gustav Fischer, 1900.)

It is with no small degree of pleasure that we have perused this, the latest, addition to the five series of "Histologische Beiträge," by Prof. Strasburger. The new volume, like some of its predecessors, deals almost exclusively with cell problems, and anything which its author may have to say on such matters must always command special respect. Breadth of treatment and open-mindedness, no less than thoroughness, have always characterised the work of this great investigator, and perhaps few who are not familiarly acquainted with the cell literature up to the early seventies can realise the extent to which our modern knowledge of cytological phenomena is indebted to the pioneer researches of the author of "Zellbildung und Zelltheilung."

In the volume before us, amongst other topics, the whole subject of what are now familiarly known as "Reduction-divisions" is treated afresh, and emphasis is laid on the need for a wider basis of comparison before we can return a satisfactory answer to the question as to whether the reduction is only *quantitative*, or whether as Weismann and his followers have supposed, it is *qualitative* also.

The majority of English and German botanical cytologists have decided in favour of the former view, and the researches of Flemming, Brauer, Meves and others on the animal side have shown that the opposite view is, at least, not always tenable. The case of the Salamander especially appears to be impossible of interpretation from the standpoint of the "Qualitative" hypothesis, and now Strasburger shows that the vitally important feature in the Salamander mitosis, viz. the *longitudinal* fission of the retreating chromosomes during the diaster stage of the first reduction division, is closely paralleled by the behaviour of the nucleus in the pollen mother cells of *Tradescantia.* Such a discovery is of the highest value as supporting the evidence already accumulated in favour of the merely quantitative character of these mitoses. The explanation which Strasburger gives of the structure of the ordinary V-shaped chromosome in the first reduction diaster will not, perhaps, gain general acceptance till it has been tested afresh. He believes that the original rod-shaped chromosome, divided longitudinally in two planes cutting each other at right angles, first splits completely into two daughter-chromosomes upon the spindle, and then that each of them opens out along the second plane of cleavage, only cohering at one end thus giving rise to the V-shaped chromosomes of the diaster. During the second division, the latter finish their longitudinal fission by complete separation of the limbs at the apex of the V, and thus what would appear to be a transverse fission proves to be merely the finish of a longitudinal splitting incepted at a much earlier period.

The author also discusses the nature of the causes which have brought about the difference of sex, and dismisses the "hunger" and autophagy hypothesis of Dangeard, which is, perhaps, a rather crude form of the less tangible but familiar theories of rejuvenescence. The view is supported that one important factor lies in the comparative absence of kinoplasm from the female, and of trophoplasm from the male, gamete. But it may, perhaps, be questioned whether the study of the evolution of sex in such forms as the green algæ does not favour the conclusion that such a difference is a result rather than a cause of sex-difference.

Incidentally, the view recently advocated by Němec, that the reproductive mitoses, in their early multipolar character, contrast with the universally bipolar vegetative divisions, is shown to be without foundation. Multipolar spindles occur both in pollen mother cells and in those of the root apex in *Vicia*, and the present writer has also observed them in the apical meristem of *Equisetum.*

The frequent connection of spindle fibres with extranuclear nucleoli is admitted, and is utilised to support the contention that these enigmatical bodies stand in a close relation to the kinoplasm which they are regarded as "activating." Many of the bodies which have, by different writers, been described as centrosomes are certainly nothing else than these escaped nucleoli, and in the example of *Nymphaea*, in which the presence of centrosomes has recently been insisted on, Strasburger shows that not only can the occasional granules not be identified as centrosomes, but that the spindle often reaches to and ends on the peripheral layer of the cytoplasm in a multipolar fashion.

Naturally the bodies known as blepharoplasts are also brought under discussion. These structures have by some been identified with centrosomes, but they seem really to be but remotely related to them. The fact that, as was shown by Webber, the true spindle often becomes multipolar, notwithstanding the presence of blepharoplasts, tells strongly against their centrosomic character, whilst the fact that in the earliest stages radiations start from them proves absolutely nothing at all. Fischer has shown how heterogeneous bodies may serve as starting-points for radiations in fixed specimens of albumin; and Guignard has described and figured, in the case of the lily, similar radiations having the entire nucleus as their common centre. Much more definite is the relationship existing between the blepharoplasts and cilia. Strasburger, who regards them as essentially consisting of kinoplasm, adduces a series of observations in support of the view that they, or bodies like them, are constantly associated with cilia. Certainly it is a fact of no small significance that whilst, in ferns and cycads, they should be absent from all the other nuclear divisions, they are constantly present in those which directly lead to the formation of the motile antherozoids. Moreover, R. Hertwig has found an analogous relation to hold good for Actinospherium, stating that "centrosomes" only occur in connection with the polar (*Richtungs*) mitoses, whilst they are quite absent from the somatic divisions.

It is not possible to touch, even briefly, on all the points raised and illustrated in Prof. Strasburger's book; it is hoped, however, that enough has been said to indicate its importance as embodying, not only a considerable number of new facts, but also many new and suggestive points of view.

And throughout the volume one is struck, not only by the full recognition accorded to the work of other investigators in the same field, but by the invariable courtesy which characterises the author's criticism of their results even when these do not accord with those obtained by himself.

J. B. FARMER.

## MODERN POWER LOOMS.

*Mechanism of Weaving.* By T. W. Fox. Pp. xxii + 514. (London: Macmillan and Co., Ltd., 1900.)

THE second edition of this excellent book, on the construction and working of the power loom, has been carefully revised by the author. It has justly been recognised as a standard text-book on the subject of loom mechanism. The work treats of tappet, dobbie, and Jacquard or harness looms. In the first place, a full exposition is given of the tappet shedding motion, reference being made to the Yorkshire tappet loom, Woodcroft and segment tappets, and also to the different under motions for the depression of the heald shafts. Proceeding, Mr. Fox deals with some of the principal types of dobbies, such as the Blackburn, Keighley, Burnley and American. By means of sectional drawings, the somewhat intricate mechanism of these dobbies is clearly described. The work would have been enhanced to the manufacturer of heavy fabrics, such as linen, woollen and worsted textures, if fuller descriptions had been given of the dobbies employed in the weaving of these fabrics. Still, to the student of cotton weaving and the manufacturer of light fabrics, the information supplied will be found invaluable, and even the makers of heavier cloths might consult the pages on dobbies with profit. It is open to dispute whether the best method of treatment has been adopted, from a student's standpoint, in dealing fully with shedding motions, including the Jacquard, and card stamping, and the methods of tieing up the harness, before reference is made to other essential motions of the loom; but the plan of the author is evident on only a casual examination of the book, namely, to treat of each distinct motion in all its various forms in succession, excluding the possibility of affording the reader at the outset even a general notion of the combination of movements in power-loom weaving. This explains why some 280 pages, or more than half the book, should be devoted to the principles of shedding, card stamping and harness mounting, prior to any descriptive reference being made to the picking, the warp let-off, fabric take-up, shuttle, and other motions.

In dealing with the Jacquard loom, the single-lift machine—the basis on which all Jacquards are constructed—is first treated of; then follow descriptions of the double-lift, centre-shed, open-shed, twilling, Bessbrooke and cross-border machines. The doup and gauze harness are very clearly explained. Other systems of tie-up, more elaborately illustrated, might have been advantageously incorporated into this section of the work; but sufficient data is afforded to enable the student to grasp the principles on which the complex mountings are effected, necessary in the weaving of tapestry and decorative silk fabrics.

Lappet weaving receives adequate attention, especially as worked by means of lappet wheels and the Scotch method; but only brief details are given on other forms of this motion, in which lags are used and pegs of different lengths, and also in which the frames for carrying the lappet threads operate on the upper side of the fabric.

In regard to picking, Mr. Fox gives some interesting information on the magnitude of the force expended in propelling the shuttle from side to side of the loom. Perhaps there is no motion in weaving in which improvement is so desirable as in picking. This is more obvious in heavy looms, where large shuttles have to be used, travelling at a high speed. Under the head of "Warp Protectors," fast and loose reeds are considered, as well as shuttle guards. Many attempts have been made at automatic warp-stop motions, such as those applied to the Northrop and Poyser looms, but probably the author has not mentioned these on account of their not having come into general use in this country; still, there are principles in both interesting to the student of "Mechanism of Weaving."

The chapter on "Multiple Box Motions" is one very typical of the author's skill in the exposition of difficult mechanical problems. Revolving, as well as drop-box motions, with suitable illustrations, are fully explained. On "beating-up," the author has some instructive information respecting the movement of the crank for carrying the batten or going part against the fell of the fabric. He supplies a table showing the motion of the crank, and treats of the length of the crank-arm and the eccentricity of movement. The concluding portions of the book are devoted to weft-stop motions, mechanism for governing the warp and taking-up of the fabric, the construction of temples and selvage motions. There is also a chapter on the arrangement of weaving-rooms or sheds, with a plate illustrative of the positions of the looms and other machinery. The book should be in the possession of all those interested in the construction of power looms.

---

## *OUR BOOK SHELF.*

*Leçons d'Optique géométrique à l'Usage des Élèves de Mathématiques spéciales.* Par E. Wallon, Professeur au Lycée Janson-de-Sailly. Pp. 343. (Paris: Gauthier-Villars, 1900.)

THIS book has been written at the desire of Prof. Wallon's students, to whom a graceful tribute is paid, in the preface, for the assistance which their questions, doubts and objections have rendered in developing the author's methods of teaching. To look on one's students as collaborators, that is certainly the secret of successful teaching; and, as here presented, Prof. Wallon's lectures are certainly successful in giving a systematic and clearly defined outline to the science of geometrical optics. The diagrams are well drawn and numerous, and the mathematical proofs are simple and yet sufficient. There is, however, little that is novel to be found in the course of these lectures; indeed, in a few cases it might be objected that there was a tendency to lag behind the times. Thus, in discussing refraction equivalents, Newton's law, that $\frac{n^2-1}{d}$ = constant, and Gladstone and Dale's law, that $\frac{n-1}{d}$ = constant, are alone mentioned ($n$ being the refractive index, and $d$ the density of the substance). Lorenz's law, that $\frac{n^2-1}{(n^2+2)d}$ = constant, is now most generally accepted. For gases, in which $n$ is nearly equal to unity, all three laws hold with about equal accuracy. But Lorenz's law appears to hold in passing from the gaseous to the liquid state, and must therefore be accepted as the most general.

An interesting chapter is devoted to the subject of the human eye, in which the most well known optical properties of that organ are discussed. In the ensuing chapter, on optical instruments, a particularly good account is given of the optical systems comprised in telescopes and microscopes of various patterns. It is surprising, however, that the ophthalmoscope and ophthalmometer are not mentioned, and are in fact so seldom found described in works on geometrical optics. Both instruments involve interesting optical arrangements, and their practical usefulness would render a description of their details still more interesting. E. E.

*Therapeutic Electricity and Practical Muscle Testing.* By W. S. Hedley, M.D., M.R.C.S. England. Pp. ix + 278; 3 plates; 99 illustrations. (London: J. and A. Churchill, 1899.)

THE increased use of electro-therapeutic methods renders the appearance of Dr. Hedley's book welcome. The profession have for some time looked somewhat askance at this departure in therapeutics, and are, in many branches of this practice, rather inclined to regard the good effect of the treatment as moral and not actual. The work before us considers the whole subject from a scientific standpoint, and any one interested in it will gain considerable profit from its perusal.

The reader must be warned at once that the book contains no mention of radiography or the application of the Röntgen rays to the healing art, either from a diagnostic or therapeutic standpoint. The author, in his preface, admits that the work is a therapeutical one, and to some extent apologises for the description of such instruments as the cystoscope, &c. No doubt he thinks the profession is in possession of sufficient literature upon the subject of radiography, which may or may not be true; the sphere of usefulness of the book would, however, certainly have been increased by the inclusion of this subject.

The work is divided into three parts. The reason for this classification is not quite evident; a part as a classification unit seems, in the author's hands, to differ to no material extent from a chapter. Further, each part is chaptered separately, which, without some very special object is to be gained, is a bad plan; from this it follows that the book contains three Chapters i., &c.

The first part is mostly concerned with those general physical considerations which have a special bearing upon what the author in the first chapter of Part ii. calls the electro-therapeutic outfit. A good account is given in Chapter vii. (p. 65) of currents of great frequency and high potential, which, as has been frequently shown, are of great therapeutic value. Much technical detail is given, both of a purely electrical and electro-physiological character.

One of the most useful chapters from the standpoint of the general physician is Chapter v. Part ii., upon the action of muscles and the consequences of their paralysis. In Chapter x. Part iii., an interesting account of cataphoresis is given. Very frequent mention is made of authors' names and no reference added, nor is there an index of authors at the end, or anything in the shape of a bibliography. Mere chance or whim has apparently guided the author in giving or omitting the full reference of a work cited; in some cases the full reference of important monographs is withheld, in others that of trivial ones given. This method cannot be too severely deprecated.

To sum up our remarks, it is with the manner and not the matter of the book we find fault. It is full of useful and, indeed, essential information to those working in this field; the author has spared no pains to collect fact bearing upon and elucidating his subject.

*Lessons in Botany.* By Prof. George F. Atkinson, Ph.B. Pp. xv + 365. (New York: Henry Holt and Co., 1900.)

THE present volume is, in a sense, an abridged edition of an excellent text-book by the same author, which appeared a year or two ago. The subject-matter is carefully arranged to suit the convenience of teacher and pupil, and altogether the book is one which should prove useful in this country as well as in America. Naturally, from the British point of view, the difficulty of obtaining the needful specimens occasionally may turn up, though this would not recur very often. We can confidently recommend Prof. Atkinson's book to the notice of teachers.

*Outlines of Plant Life, with special reference to Form and Function.* By Prof. Charles Reid Barnes. Pp. vi + 308. (New York: Henry Holt and Co., 1900.)

THIS is a work intended for school use. It has some points of merit, especially the special part on ecology, in which the examples are well chosen and fully illustrated. The illustrations, though almost all are (with due acknowledgment) borrowed from other works, are distinctly good. We think the book a useful one, and the exercises which are interspersed through the volume add to its value.

## *LETTERS TO THE EDITOR.*

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Note on some Red and Blue Pigments.

THE following data are placed on record because interesting in themselves, and in the hope that they may be useful to others who have the opportunity to make further investigations.

(1) A little boraginaceous plant called *Eremocarya micrantha* (Torrey) is common in sandy places at Mesilla Park, New Mexico, flowering in April. A few days ago, Prof. E. O. Wooton called my attention to the fact that its roots are deep red, and stain herbarium paper. Curious to learn more about this peculiar coloration, I made some tests, with the following results:—The pigment is not soluble in water, but it readily dissolves in cold alcohol, forming a beautiful red solution. The roots, after being treated with alcohol, become white, showing that the pigment is entirely superficial, and is apparently an excretion from the root. The red colour is that of the normal or acid state of the pigment, but on adding enough liquor potassæ to make the solution alkaline, the colour immediately becomes a beautiful blue. An excess of strong caustic potash does not destroy the pigment until after a considerable time. Prof. A. Goss tested the delicacy of the colour-reaction in the presence of acids and alkalis, and found that a very small excess of one or the other would give the characteristic colour. The pigment is, of course, an anthocyan, very similar, at least, to litmus; and it may be that it can be utilised for the same purposes.

(2) It has been remarked more than once that whereas the hind wings of Acridiidæ (grasshoppers) are sometimes blue, sometimes red, and sometimes yellow, species living in the same locality, though of very diverse genera, will often have similarly coloured wings. In the Mesilla Valley we have common species with red and with yellow wings; but in the Organ Mountains, not far away, I found two species very abundant, both having blue wings, and otherwise coloured much alike, though of totally different genera. These were *Leprus wheeleri* and a *Trimerotropis* which I took for *T. cyaneipennis*, but which Mr. S. H. Scudder tells me is distinct and apparently undescribed. As the blue of the wings appeared to be certainly a pigmentary colour, and much resembled the vegetable anthocyans, I detached one of the wings of *Leprus wheeleri*, and boiled it in dilute hydrochloric acid. As I had hoped, but hardly ventured to expect, the blue at once became red. Heating the thus reddened wing in liquor potassæ did not change it back to blue, but caused it to turn yellow. I infer that the blue pigment has a red (acid) phase, but that strong alkali will destroy it altogether, leaving a yellow coloration which is of a different character. It is difficult to avoid the conclusion that the redness or blueness of the wings in these grasshoppers may result from the action of some environmental factor (*e.g.* the juices of plants eaten) upon the pigment, and that this accounts for the colour-similarity of diverse species living at the same place. Of course, this is not supposed to account for the similarity of the colours of the tegmina and thorax, of which the various shades of grey, red and brown resemble those of the rocks and ground.

T. D. A. COCKERELL.

Mesilla Park, New Mexico, U.S.A., April 17.

### Valve Motions of Engines.

IN your number of December 14, 1899, Prof. John Perry mentions a diagram by Mr. Harrison. This diagram is the same as "Das bizentrische polare Exzenterschieberdiagramm" of F. A. Brix in the *Zeitschrift des Vereins Deutscher Ingenieure*, April 10, 1897.

There is only a small difference, as Mr. Harrison finds the distance OC by means of a circle with radius = length of connecting-rod, and Mr. Brix finds that distance by calculating it out of $\frac{R^2}{2L}$, (R = length of crank, L = length of connecting-rod). Now OC has not exactly that value, but the fault made therewith is much smaller than the fault made by describing the circle. Therefore the method of Mr. Brix is preferable to that of Mr. Harrison.

F. J. VAES.

Rotterdam, April 14.

MR. BRIX seems to have solved only the simple case of a valve worked by an ordinary eccentric. There are other good graphical solutions—for example, by Coste and Maniquet in a modified form of the Reauleaux diagram, which gave accurate results. Mr. Harrison's diagram is more general and is applicable to link and radial valve-gears and to all motions which are composed of a simple harmonic vibration with a small octave superposed. It may be used for velocities and accelerations as well as mere displacements. As to calculating the distance OC by the formula $\frac{R^2}{2L}$, instead of using the construction of the circular arc, this is a matter of no importance because there is no appreciable difference in the answers.

April 28. JOHN PERRY.

### Drunkenness and the Weather.

I NOTICE in your issue of March 15 a communication from Mr. R. C. T. Evans, of Gray's Inn-road, W.C., calling attention to a probable error in my deductions in the paper which appeared in your issue of February 15, under the title "Drunkenness and the Weather." He says, "When a man is intoxicated and commits an assault, the result is entered in the police reports as 'assault,' the more serious offence overshadowing the less; so that in all probability many of the cases of assault referred to in the statement were also cases of drunkenness, but were not tabulated as such. Studying Prof. Dexter's curves in this light, we may reasonably conclude that the number of those arrested for drunkenness or its results, varies but little throughout the year."

Although his supposition seems a reasonable one, a fuller statement of the conditions of the study will show that the fluctuations of the "drunkenness" curve cannot be so easily accounted for.

First, the monthly occurrence of arrests for drunkenness for New York City is more than twice that for assault, even in the summer, when the former are at the minimum and the latter at the maximum for the year, and if we suppose that every person arrested for assault in the summer was also intoxicated and would have come into the hands of the law for that crime if he had not for the other, even this would not bring the drunkenness curve up to its normal for the winter months.

Second, the method of recording crime by the New York City Department of Police makes this practically impossible. Misdemeanours are there classified and recorded under 183 different headings. The two which I have compared are "assault and battery" and "intoxication." There are, however, four other classes of assault besides, one for "intoxication and disorderly conduct," equalling that of "assault and battery" in the annual number of arrests, besides one for "fighting." A letter just received from the Clerk of Police says, "The crime of intoxication and fighting—a drunken brawl—would be classified in the statistics as 'intoxication and disorderly conduct.'" A careful analysis of all the conditions would make it seem that only occasionally would arrests for "assault and battery" encroach upon the data of drunkenness. I believe they might sometimes do so, but not sufficiently often to materially influence the curve.

EDWIN G. DEXTER.

Greeley, Colo., April 17.

## *SOME SPECULATIONS AS TO THE PART PLAYED BY CORPUSCLES IN PHYSICAL PHENOMENA.*

IN some experiments described in the *Phil. Mag.* October 1897, I showed that in the kathode rays there were present bodies whose mass was exceedingly small compared with the masses of ordinary atoms; these masses, which carry a charge of negative electricity, I called "corpuscles." Ever since then I have indulged in speculations as to the possibility of these corpuscles existing in a free state in ordinary matter not under the influence of the very intense electric field which are associated with the kathode rays. As recent work has produced some evidence of the free existence of these corpuscles, I have thought that these speculations might be of some interest to a wider circle than that to which they have hitherto been addressed. In the *Phil. Mag.*

(February 1900), I showed that these corpuscles existed in the neighbourhood of a hot wire and of a metal plate illuminated by ultra-violet light, and recently the discovery by Giesel, Curie and Becquerel of the magnetic deflection and electric charge carried by part of the radium radiation may be interpreted as indicating the existence of corpuscles in this substance.

I suppose, then, that there is a certain amount of what may be called corpuscular dissociation taking place in bodies; that some of the molecules of the substance are continually breaking up by the detachment of a corpuscle, and are being reformed by the arrival of another corpuscle; the result of this is that at each instant there are a certain number of free corpuscles with negative charges distributed throughout the body, while the corresponding positive charges are on the molecules of the body, the corpuscles are much more mobile than the molecules; indeed, in solids and liquids, the latter may be regarded as almost fixed in comparison with the former. We thus get the conception of a body permeated with corpuscles which are able under forces to move from one part of the body to another. We must remember that, as the particles are charged, any movement will be accompanied by electrical effects and, in general, a volume density of electrification.

The actual number of corpuscles free at any instant is the result of an equilibrium between the number of corpuscles produced by dissociation and the number which recombine. Thus if $q$ is the number of corpuscles produced by dissociation in unit volume in one second, $\tau$ the time during which a corpuscle is free (*i.e.* the time which elapses between its departure from one molecule and its entry into another), $n$ the number of free corpuscles in unit volumes, then when there is equilibrium $q=n/\tau$ or $n=\tau q=\lambda q/u$, if $\lambda$ is the mean free path of the corpuscle and $u$ its velocity of translation. In non-conductors we suppose that there are very few corpuscles, but that they are abundant in metallic conductors. Let us now trace some of the consequences of the existence of these corpuscles in a solid, and suppose for the moment that the positively charged molecules are fixed; if the corpuscles are acted upon by gravity (of which point we have no evidence), then in a vertical bar of metal the number of corpuscles in unit volume will be greater at the bottom of the bar than at the top, for just the same reason as the density of the air gets less as we go higher; thus in this case gravity would produce a displacement of electricity, the bottom of the bar being negatively and the top positively electrified. Again, in a rotating mass of metal the centrifugal force would tend to drive the corpuscles towards the surface; there would thus from this effect be an excess of the corpuscles near the surface and a deficit near the axis. Thus the outer parts of the metal would be negatively and the inner parts positively electrified, the rotation of the negatively electrified corpuscles being no longer completely balanced by that of the positively electrified molecules would give rise to a magnetic field; thus a large mass of rotating metal would act as a magnet. Again, suppose we place a piece of metal in a magnetic field, the action of the magnet on the moving corpuscles will make them describe curved paths, and we can easily see that the magnetic effect due to the particles moving in this way is in the opposite direction to that of the external magnetic field. Thus a metal containing these corpuscles would tend to act like a diamagnetic substance. Again, suppose the metal is exposed to an electric force X, the corpuscles will acquire an average velocity along $x$ equal to $X\tau e/2m$, where $m$ is the mass of a corpuscle and $e$ its charge. Let us call this velocity $v$X, then the electric current across unit area is $nev$X; thus $nev$ or $qe^2\lambda^2/2mu^2$ is the specific conductivity of the substance. If we suppose that $u$, the mean velocity of translation of the corpuscles, varies with the temperature in the same way as the velocity of translation of the molecules of a gas, $mu^2$ would be proportional to the absolute temperature, and the specific resistance would, considered as a function of the absolute temperature $\theta$, vary as $\theta/q$; if $q$, the amount of ionisation increases as the temperature increases, the resistance will vary more slowly than the absolute temperature; if $q$ diminishes as the temperature increases, the resistance would vary more rapidly than the temperature. These corpuscles moving from place to place would carry not merely electric charges, but energy from one part to another; and since the coefficient of diffusion of these corpuscles is proportional to $v$, the thermal and electric conductivities would be proportional to each other. Again, when we have conduction of heat we have unequal streams of these corpuscles in opposite directions; thus the unequal deflection of their paths produced by a magnet would give rise to an electric displacement, and we should have an electromotive force at right angles to the magnetic force and to the temperature gradient, an effect discovered by v. Ettinghausen and Nernst. From the conductivity of the gas we can deduce the value of $nev$. We know the value of $e$, and hence another equation would enable us to determine $n$ and $v$; for this purpose we turn to the Hall effect, but here the results are disappointing, for we can easily prove that when $E^1$ and E are the tranversal and longitudinal electric forces and H the magnetic force, $E^1/EH = \frac{v_1k_2 - v_2k_1}{k_1 + k_1}$, where $v_1$ and $v_2$ are respectively the velocities of the negative corpuscles and positive molecules under unit electric force, and $k_1$ and $k_2$ the values of $k$ for these ions where $k$ = pressure ÷ number of systems in unit volume. If both the negative corpuscles and the positive molecules behave like perfect gases, $k_1 = k_2$ and $E^1/EH = \frac{1}{2}v_1$, since $v_2$ is very small; thus, on this supposition, the Hall effect would give us the value of $v$; but there seems no reason to suppose that the positively electrified molecules in the solid would produce the same pressure as an equal number of molecules in the gaseous state, and thus though $v_2$ is small compared with $v_1$, $k_2$ may be so small compared with $k_1$ that $k_1v_2$ cannot be neglected in comparison with $k_2v_1$, and in this case the Hall effect would not be sufficient to determine $v$. The fact that the Hall effect is of different signs for different substances shows that we have to take into account both terms in the expression for $E^1/EH$.

Again, if different parts of a metal bar were at different temperatures, the "pressure" as it were of these corpuscles would be different at different parts of the bar, so that the corpuscles would tend to flow from one part of the bar to the other, and cause an electric displacement; thus difference of temperature would cause an electric displacement. This is the Thomson effect, measured by the "specific heat of electricity." The value of the "specific heat of electricity" will on this theory depend not only on the variation with temperature of the kinetic energy of a single corpuscle, but also on the way the dissociation constant $q$ varies with the temperature. There are many other phenomena which can be interpreted in terms of these corpuscles, but these I must leave for another occasion.

J. J. THOMSON.

Cavendish Laboratory, Cambridge, April 30.

## SCIENCE IN RELATION TO ART AND INDUSTRY.

AT the annual banquet of the Royal Academy on Saturday evening, Sir Norman Lockyer, in replying on behalf of science, made the following remarks upon the intimate relation between intellectual progress and the study of nature, and also upon the necessity for a more liberal provision for scientific work if England wishes to compete successfully with other nations struggling for industrial supremacy. Though the public mind may be disturbed by the statement of the principle that the provision made for scientific and technical study and research should be as great as that given by any two other nations, the comparison will serve a useful purpose in directing attention to a view of the claims of science worthy of consideration.

It is a very great honour for a student of science to be called upon in such an august assembly as this to say a few words; but if I am to be accepted as the representative of science I do not wish to be fettered by your suggestion, Sir, that I should refer to the dependence of art on science. I am sure that I may frankly say for every man of science that we acknowledge freely the firm brotherhood between art and science—a brotherhood founded upon a common object, the study of Nature, "the mistress of all the masters," and carried on by a common method, the proper co-ordination of brain, hand and eye. In every case with which a man of science or a man of art has to deal, imagination is required, and so science and art meet upon terms of mutual helpfulness. I think I may also say that this feeling is thoroughly reciprocated by men of art, for many of them honour me with their friendship, and therefore I know their sentiments. I am the more anxious to say this because some twenty years ago, when I was privileged to attend this anniversary dinner, I heard a distinguished representative of literature express a totally different sentiment. He told us that "before their sister, Science, now so full of promise and pride, was born, there were Art and Literature like twins together," and it was suggested that the sooner art and literature formed an alliance offensive and defensive against the interloper, the better it would be for them. I do not believe in this. For me science is as old as art. They have both advanced together. Let us take the position of things 6000 years ago, to begin at the beginning of things, if we can. Then the priest-mummifiers of Memphis had to be profound anatomists. If you go to the Gizeh Museum you find magnificent specimens in those statues of Chepren in diorite, other statues in wood, and the plaques, veritable Memlings in stone, which clearly show that this knowledge was also possessed by their sculptors. If you come down to a comparatively modern period, something like 600 B.C., and compare those wonderful metopes of Solinunto with the marbles of the Parthenon, which are of a later date, you will find an enormous advance in the latter. You will find that Hippocrates had lived in the interval, and, indeed, that he and Phidias were contemporaries and fellow-townsmen. Carrying the matter down to the introduction of Universities into Northern Italy in the thirteenth century, we find that the difference between the art of Cimabue and Giotto depends on the fact that anatomy had been introduced in the meantime. Science, then, is no new interloper, seeking to detract from the importance of art and literature. What was new twenty years ago was that the work of the late Prince Consort, whose name will always be revered by those who know the benefits he conferred on our country, was then beginning to tell. He showed us that in order to secure industrial progress we must have, above all things, instruction and practice in science and art. In war, being well assured of the valour and endurance of our sailors and soldiers, the chief thing we have to do is to see that they are properly supplied with the engines and munitions of war, and, more than these, the scientific spirit. In peace, for the beauty of a nation's life and a perfect record of it, we must look chiefly to the sweetening and ennobling influences of art and the enduring works of its masters; but for a nation's continued welfare and progress both science and art are necessary. We are in face of industrial struggles, and we must utilise both science and art to supply the wants of our own and other countries, and to provide commodities made in England, besides handling

> "Things of beauty, things of use,
> That one fair planet can produce,
> Brought from under every star."

We are in face of a struggle for existence in which we know full well that only the fittest will survive. How are we going to carry on the struggle? What are our weapons? Our first line of defence in this direction can only consist of our Universities and our teaching centres. Have we enough of them? We know already that we have not enough of them, because we have already lost several important engagements in these industrial battles. Are there no means by which we can judge of their sufficiency? In relation to non-peaceful international struggles in which also defeat has to be guarded against, a clear and universally approved policy has been enunciated; this is, that the future of our empire, an empire the real unity and strength of which are developing under our eyes at this moment, can be secured if we see to it that our first line of defence, our fleet, shall be equal in strength to the fleets of two other possibly contending powers. The second answer then, I think, is that this principle should be applied to our first line of defence in those industrial conflicts the results of which are much more enduring. Do our teaching and research centres at present outnumber in the same proportion, as do our ships, those of any two nations which are actually contending with us in peaceful enterprise? And, also, are they equally efficient in every respect? I believe, and I know that this view is held by many representative men of science, that until our Universities, our science schools, our art schools, and our technical institutions bear the same relation both in number and efficiency to those of other nations as do our battleships, cruisers, and small craft, we shall not be justified in regarding the future of the empire with that freedom from care which is the attribute of a strong man armed.

---

## NOTES.

PROF. E. SUESS, professor of geology in the University of Vienna, has been elected a Foreign Associate of the Paris Academy of Sciences, in succession to the late Sir Edward Frankland. Sir John Burdon-Sanderson, Bart., has been elected a Correspondant of the Academy, in succession to the late Sir James Paget.

DR. S. L. TÖRNQUIST, of Lund (Sweden), has been elected a Foreign Member of the Geological Society, and Prof. F. Sacco, of Turin, has been elected a Foreign Correspondent.

WE much regret to see the announcement of the death of Lieut.-General Pitt-Rivers, F.R.S., the distinguished anthropologist, on Friday last.

THE annual conversazione of the Society of Arts will be held at the Natural History Museum, South Kensington, on Wednesday evening, June 20.

THE adjourned debate on the Sea Fisheries Bill was resumed in the House of Commons on Monday. After a long discussion, a division was taken, and a majority was obtained in favour of the second reading. The Bill was then referred to a Select Committee.

IT is reported that Vesuvius has shown signs of increased activity during the past few days. Explosions have taken place in the crater of the volcano, and masses of rock and lava have been ejected. The huts of the guides and the topmost station of the funicular railway are threatened. Reuter reported that four Englishmen who ascended Vesuvius on Tuesday went beyond the limit indicated as dangerous by the guides and gendarmes, and were seriously injured by a mass of ejected material striking them. This however has since been denied by Reuter's Naples Correspondent.

THE U.S. National Academy of Sciences has decided to award the Barnard medal to Prof. Röntgen for his discovery of the X-rays. This medal is awarded at the close of every quinquennial period for a discovery in physical or astronomical science, or novel application of science to purposes beneficial to the human race. The first presentation of the medal was to Lord Rayleigh and Prof. Ramsay for their joint discovery of argon.

REUTER'S AGENCY learns that Dr. Louis Sambon and Dr. G. C. Low, who has been awarded the Craggs research scholarship of 300*l.* per annum, are about to experiment with a view to proving that malaria is spread by mosquito bites, and expect to begin work seriously on June 1, by which time they will have all their arrangements completed. A suitable spot has been chosen for the erection of their mosquito-proof house in the Campagna, on the line of the railway running from Rome to Tivoli.

A MEETING of the International Association for the Advancement of Science, Arts and Education will be held at the Society of Arts to-morrow (May 11), at 4 p.m. Sir Archibald Geikie, F.R.S., vice-president of the British Committee, will preside. The secretary, Prof. Patrick Geddes, will deliver an address on the nature and aims of the Association and its forthcoming assembly at the Paris Exhibition.

IN connection with the International Congress of Physics to be held in Paris from August 6 to 12, a preliminary programme of papers has been issued. Over sixty reports have already been promised, and among the names of contributors we notice those of Amagat, Arrhenius, d'Arsonval, Battelli, Becquerel, Blondlot, Bouty, Boys, Branly, Brillouin, Broca, Cornu, Curie, Exner, Griffiths, Hurmuzescu, Lippmann, Lorenz, Poincaré, Potier, Poynting, Pringsheim, Righi, Spring, J. J. Thomson, Villard, Warburg and Wien.

THE next meeting of the Comité International des Poids et Mesures is fixed for September 10, 1900. Owing to the death of M. Joseph Bertrand, and the resignation of Prof. Thalen, two of the original members of the Comité, the number of members is now limited to eleven. Great Britain will be represented at the forthcoming meeting by Mr. H. J. Chaney, a member of the Comité.

THE death of M. Edouard Grimaux, at the age of sixty-five, occurred during the past week. M. Grimaux succeeded Cahours as professor in the École Polytechnique at Paris, and also held a chair at the Agronomic Institute. He made numerous and valuable contributions to organic chemistry, and was the author of several chemical treatises. He will be gratefully remembered by chemists for an admirable biography of Lavoisier, which he published in 1884. M. Grimaux lately became prominent in connection with the Dreyfus case. At the Zola trial he expressed his belief in the innocence of Dreyfus. For this he was deprived of his professorship by General Billot, notwithstanding the fact that he had rendered devoted service to the army in 1870. In 1894 M. Grimaux was elected to the Academy in the place of Frémy.

REPLYING to a question in the House of Commons on Monday, Mr. Akers-Douglas stated that the new National Physical Laboratory is not to be erected, as has been reported, in the Queen's Cottage grounds, or in any other grounds attached to Kew Gardens. It will stand quite outside those Gardens on Crown land. The only part of the scheme which might possibly be supposed to affect the amenities of the Gardens is a small building which will not, at the outside, cover a quarter of an acre. This building will be so placed as not to interfere with the views from the Gardens over the Old Deer Park, and it will not be opposite to that part of the Gardens round the Queen's Cottage which is reserved in a wild state. The building will only be used for delicate scientific work which will not disturb the seclusion of the neighbourhood of the Queen's Cottage, and which, in fact, itself requires as much quiet and privacy as can be obtained.

THE Paris correspondent of the *Chemist and Druggist* states that science is represented at the Salon by several portraits of average merit. The best is that of Dr. Vaillard, head army surgeon and professor at the Val de Grace Military Hospital, where he is known to two or three generations of army pharmacists who have followed his lectures. Dr. Vaillard is of middle age, and is shown standing, in regimental dress, with the Cross of the Legion of Honour on his tunic. His left hand is leaning on a laboratory-bench, on which are a microscope and a variety of analytical appliances. To his right is a lecture-blackboard, and one can dimly see his written demonstration. The artist is M. Paul Bourdier. The portrait of M. Hautefeuille, chemist, and member of the French Institute, is the work of a lady artist. She shows him in everyday attire in a corner of his laboratory, sitting at a table, with a collection of scientific apparatus near at hand; in the background is a furnace, at which an assistant in a white blouse is working. M. Tisserand, of the French Institute, is another portrait of fair merit. One would like to see more of this class of picture, but must suppose artists find no market for them.

THE death of Dr. Edmund Atkinson on the 4th inst., after a very short illness, will be a matter of deep regret to his large circle of friends. He was born at Lancaster in 1831, and was a student of Owens College, Manchester, in the early days of that institution. There he became assistant to the late Sir Edward Frankland, the first professor of chemistry in the College, and was associated with him in organising the laboratory which has since become so well known. About 1854 he went abroad for some years and continued his scientific studies at the Universities of Marburg, Göttingen and Heidelburg, and at the École de Médecine in Paris under Wurtz. On his return to England he became private assistant to Sir Benjamin Brodie at Oxford, then science master at Cheltenham College, and afterwards professor of experimental science at the Royal Military College, Sandhurst, and at the Staff College. He was several times elected upon the council of the Chemical Society, and was one of the founders of the Physical Society, of which Society he was treasurer from the beginning until the last anniversary meeting, with the exception of a short interval a few years ago. Dr. Atkinson rendered great service to science by his numerous translations into English of foreign scientific works; among these the best known are Ganot's "Elements of Physics," von Helmholtz's "Popular Scientific Lectures" and Mascart's "Treatise on Electricity and Magnetism." He was a man of excellent judgment in practical affairs, and of late years he gave much time as a magistrate to the local affairs of his neighbourhood. He was always ready to undertake onerous duties for those in need of help, and was a most generous and steadfast friend.

THE council of the Royal Geographical Society have awarded the two Royal medals for this year to Captain H. H. P. Deasy and Mr. James McCarthy. The Founders' medal has been awarded to Captain Deasy for the exploring and survey work accomplished by him in Central Asia. Mr. McCarthy is the Government surveyor of Siam, and the Patron's medal has been awarded to him for his great services to geographical science in exploring all parts of the kingdom of Siam, for his laborious work during twelve years in collecting materials for a map, to form the basis of a survey system, and for his admirable map of Siam just completed. The other awards have been made as follows:—The Murchison award to M. Henryk Arctowski for the valuable oceanographical and meteorological work which he performed on the Belgian Antarctic expedition; the Gill memorial to Mr. Vaughan Cornish for his researches, extending over several years, on sea-beaches, sand-dunes, and on wave-forms in water; the Back grant to Mr. Robert Codrington for his journeys in the region between Lakes Nyassa and Tanganyika, during which he removed, on behalf of the Society, the section containing the inscription from the tree under which Livingstone's heart was buried; and the Cuthbert Peek grant to Mr. T. J. Alldridge for his journeys during the past ten years in the interior of Sierra Leone, during which he has done valuable geographical work.

THE following opportunities for the study of botany during the ensuing summer season in the United States are mentioned in the *Journal* of the New York Botanic Garden for April:—Columbia University, New York, has instituted a summer session, beginning July 2 and ending August 10. The department of botany will be under the charge of Prof. Lloyd, who will offer courses in ecology, general botany, and research work in select subjects. Students in these courses will have access to the museum and collections of the Botanic Garden. The Woods Holl Laboratories will be open from July 5 to August 16, and the botanical staff includes Dr. B. M. Davis, Mr. G. T. Moore, Dr. R. H. True, Miss Rhoda A. Esten, and Miss Lillian G. MacRae. Courses in cryptogamic botany, plant physiology, and plant cytology will be offered. The biological laboratory at Cold Spring Harbour will be open from July 2 to August 25, the botanical staff including Dr. D. S. Johnson, Dr. H. C. Cowles, and Mr. W. C. Coker. Courses of lectures will be offered in cryptogamic botany, ecology, and bacteriology.

THE Annual Summary of the *U.S. Monthly Weather Review* for 1899 contains a very interesting account of the climate of St. Christopher, by Mr. W. B. Alexander. The island lies in latitude 17° 20′ N. and longitude 65° 45′ W.; its length is 23 miles, and the breadth of the main body is about 5 miles. The central part is occupied by a range of mountains, the highest of which, Mount Misery, rises to a height of about 4100 feet. Tables and diagrams are given showing the barometric pressure for 35 years, and the rainfall for 44 years at Basseterre, which is situated in a spacious and fertile valley. The climate, generally speaking, is dry and healthy, being tempered and purified by frequent thunderstorms. The mornings and evenings of the hottest days, which occur in August, are agreeably cool; the coldest months are January and February. The mean annual temperature is about 81°, of August, 83°, and February, 78°. The mean annual rainfall is about 51·6 inches; 37 per cent. of the amount occurs during the first half of the year, and 63 per cent. during the last half. The rainfall is more frequent than heavy; it has only reached or exceeded 5 inches in 24 hours eleven times in 44 years.

IN the *Proceedings* of the South African Philosophical Society, vol. xi., Mr. J. R. Sutton publishes an important discussion of the winds of Kimberley. The results are obtained from three years' hourly observations with Osler and Robinson anemometers. The period is admittedly short; but the excellence of the position and the scarcity of hourly observations in South Africa are quoted as reasons for not delaying the appearance of the paper. The observatory is situated at Kenilworth, about three miles N.N.E. of Kimberley, at an altitude of nearly 4000 feet. It has been supposed that there was an overwhelming excess of northerly winds, and theories have been propounded why this is the case; but the conclusion to be drawn from the paper is that while sometimes one and sometimes another direction may preponderate from year to year, a definite prevailing wind does not exist. Of the 25,898 hours of wind analysed throughout the three years, the final resultant contains the small components of only 50 hours to the north and 100 hours to the west. The diurnal curve of wind velocity contains two maxima (2h. p.m. and 10h. 45m. p.m.) and two minima (5h. a.m. and 7h. 30m. p.m.). The mean hourly velocity is 6·6 miles per hour.

AN interesting illustration of Doppler's principle is noted by Prof. F. Richarz, of Greifswald. The writer was standing by the Brenner Pass near a curve where a railway train was approaching him, the line being backed by a wall of mountain. On the engine giving a short whistle, an echo was heard, the pitch of which was at least half a tone lower than the original sound.

THE American Museum of Natural History, New York, as we learn from a note recently published by Mr. J. A. Allen, has recently obtained a specimen of the head of the wood-bison (*Bison americanus athabascae*), which is still in existence in the forests near Great Slave Lake. Compared with the bison of the plains (now extinct in a wild state) the woodland bison is stated to be rather larger than the former, and to have the bases of the horn-cores relatively thicker. In 1894 the herd of wood-bisons in the Great Slave Lake district was estimated to be some hundreds in number, but in 1899 it was reduced to about fifty. A very few years more will probably witness the complete extinction of this animal.

AT a recent meeting of the Geographical Society of France, the well-known naturalist, M. Grandidier, the author of the great work upon the natural history of Madagascar, gave an account of his last expedition to that Island, in 1898–99. M. Grandidier landed at Tuléar, on the south-western coast of the Island, and thence made an adventurous journey through the interior to Fianarantsoa, in the Betsileo country, in the south-eastern district. M. Grandidier on his way visited the well-known deposits of Ambolisatra, about 35 kilometres north of Tuléar, where numberless fragments of *Aepyornis*, and almost entire skeletons of the small Madagascar hippopotamus, besides remains of many lemurs of gigantic size and other extinct animals were obtained. From Fianarantsoa, M. Grandidier proceeded north through a well-known country to Antananarivo, the capital of the Island.

AS in the case of other larger mammals, the process of dividing the giraffe (*Giraffa camelopardalis*) into "sub-species" is now proceeding apace. Mr. de Winton (*P.Z.S.* 1897, p. 273) first showed, on good grounds, that the giraffe of South Africa was, in certain points of structure, different from the giraffe of the Sahara and Nubia, and proposed to call the former *Giraffa capensis*, leaving the old name *Giraffa camelopardalis* for the northern form. Since then, Mr. O. Thomas (*P.Z.S.* 1898, p. 40) has separated the giraffe of Upper Nigeria from the northern form under the title *Giraffa camelopardalis peralta*. Still more recently, Herr Matschie, of Berlin (*Sitzb. ges. Nat. Fr.* Berlin, 1898, p. 75), has added two new names to the list of giraffes, and called them after their discoverers, *G. tippelskirchi* and *G. schillingsi*, the former being from German East Africa, and the latter from British East Africa. It is curious that these two closely adjoining districts should not agree even in having the same form of giraffe!

THE *Quart. Journ. Micr. Science* for April contains an account by Monsieur P. Bouvier of the results of his examination of the specimens of the primitive Arthropods, commonly known as *Peripatus*, in the collection of the British Museum. The author, who adopts the generic divisions proposed by Mr. Pocock, names one new Andean form after the Director of the Museum, and shows that, with the exception of one from the Congo and a second from Sumatra, all the representatives of the typical genus *Peripatus* are American. To the same journal Mr. E. Warren communicates a paper on the individual differences exhibited by one of the water-fleas (*Daphnia magna*) in its power of withstanding the introduction of salt into the water in which it lives. The physiological condition of the individual is found to have a great effect on it salt-resisting powers.

IN the last issue of the *Zeitschr. Wiss. Zool.*, Dr. R. Gast relates the life-history of a rotifer of the genus *Apsilus*, specimens of which were recently found in an aquarium at Leipzig. This paper is followed by one on the development of a sponge of the group Sycones by Dr. O. Maas, which is worthy of special notice on account of the beauty of the illustrations.

MENTION has already been made in these columns of the description in the *Notes* from the Leyden Museum of the crustaceans collected during the Dutch Expedition to Central Borneo. In the March issue of the same serial this is followed by an account of the birds, which have been worked out by Dr. Büttikofer. Although expectations were entertained that many new forms would be obtained, out of 269 species collected all were previously known, and only two were new to Borneo.

THE April number of the *Journal of the Quekett Microscopical Club* contains the description, by Mr. J. G. Waller, of a new marine British sponge, obtained some twenty years ago at Torbay, for which the name *Raphiodesma affinis* is suggested. Another addition to the British fauna is a new species of Hymenoptera (*Prosopis palustris*), from Wicken Fen, Cambridgeshire, described by Mr. R. C. L. Perkins, in the *Entomologist's Monthly Magazine* for March. This discovery should strengthen naturalists in their opposition to the proposed draining of the fen in question.

MANY strange objects are worn by savage peoples, and for various reasons, also, as with us, rarity usually enhances value. In the Pelew Islands the rubbed-down first vertebra (atlas) of the dugong is worn as a bracelet by the more important men, for it is not often that the vertebra in question is large enough to be so worn. The "klilt," as it is called, has recently been fully described and figured by Dr. O. Finsch (*Globus*, lxxvii. 1900, p. 153). In the Timor Group a wooden imitation is employed; but in Timorlaut the second vertebra (axis) of the dugong is employed; but, although the dugong is greatly hunted in Torres Straits and in South-eastern New Guinea, no ornaments are made from its bones or tusks.

DR. HERMANN MEYER gives an account of a second journey to explore the head waters of the Xingu, in the *Verhandlungen* of the Berlin Gesellschaft für Erdkunde. The route taken was from Cuyaba, reached by ascending the Parana–Paraguay from Buenos Ayres, over the watershed and down the Ronuro to its junction with the main stream, and back to Cuyaba up the course of the Kulischu; practically the same as the former journey of 1896–97, except that the Ronuro was followed throughout its length instead of the Jatoba, a tributary joining it in its lower course. Dr. Meyer concludes that later expeditions will avoid the Ronuro; the Kulischu gives the best access to the region, an exploration of which as far as the Paranayuba would give valuable scientific results.

THE new number of the *Mittheilungen von Forschungsreisenden und Gelehrten aus den deutschen Schützgebieten* contains some interesting papers from the German East African region. Captain Kannenberg gives the first part of an account of a journey through the Marénga Makāli region, with a map. The pendulum expedition under Dr. Fulleborn and Lieut. Glanning reports progress. A summary of the results of the geological expedition in the region north of Lake Nyassa under Dr. Danz is given, and Lieut. Baumstark contributes a paper on the Warangi.

DR. H. NAGAOKA has contributed a valuable paper on the elastic constants of rocks and the velocity of seismic waves to the *Publications* of the Japanese Earthquake Investigation Committee (No. 4 in Foreign Languages). His experiments were made on about eighty specimens of different rocks, cut into prisms 15 cm. long and nearly 1 cm. square in section. They showed at once that Hooke's law does not hold even for very small flexure and torsion, the deviation being prominent in certain specimens of sandstone, and more marked in torsion than in flexure experiments. On releasing the rocks from stress, the return to the original state is extremely small. The elastic constants of archæan and palæozoic rocks (whether of igneous origin or otherwise) are far higher than those of cainozoic rocks, though the velocity of elastic waves in them is not higher in the same proportion. So far as the experiments go, the elastic constants increase more rapidly than the density, so that the velocity must be greater in the interior than at the surface of the earth's crust.

WE have received the Twenty-fourth Annual Report of the Geological and Natural History Survey of Minnesota for the years 1895–98; a report which is stated by Mr. N. H. Winchell, the State Geologist, to be his final one. As he remarks: "It ought not to be supposed that by the closing of active work by the present survey, and the publication of its final report, the geology of the State is a finished thing. Geology is a progressive science, and requires continual work." Other States have had surveys which have been hurried to "completion," and have naturally had to enter upon re-surveys, more careful and elaborate. Our own Geological Survey has experienced this as much as any of those abroad; where impatience to see the work "completed" and smallness of revenue have hampered and retarded real progress. The report before us contains a synopsis of the field-work done in Minnesota since 1894, and a useful alphabetical index to the entire series of annual reports of the Survey. Mr. Winchell also notes some of the more important economic and scientific researches which should be carried on in a future survey of the State.

IN the "Palæontologia Indica" for 1899, there is a description of the Cambrian fauna of the Eastern Salt-range, by Dr. K. Redlich, who has supplemented the work of Waagen with more detailed information. A new genus, *Hoeferia*, is now established for the specimens previously referred to *Olenellus*. Among other fossils described are *Hyolithes*, *Lingulella* and *Pseudotheca*. The name *Cylindrites* is applied to "long cylinders, which are often arranged in a fan-shaped aggregate," and appear to be worm-tracks; but it may be pointed out that the name was long ago applied to a genus of Gasteropods. None of the Cambrian fossils from the Salt-range can, in the author's opinion, be referred to a later horizon than the *Paradoxides*-zone. Dr. F. Noetling contributes notes on the morphology of the Pelecypoda, dealing with the hinge of some Miocene and recent bivalves. He endeavours to show that the shape and the delicate and minute variations in the shells can to some degree be expressed better by figures than by words. Dr. C. Diener describes the Anthracolithic fossils of Kashmir and Spiti. In studying the collections made by the Geological Survey of India, he came to the conclusion that fossils both of Permian and Carboniferous ages were included in the series; and he uses the term Anthracolithic as a convenient one for a Permo-Carboniferous group, which appears to be intimately connected stratigraphically and palæontologically. Among the specimens described, the presence of many European types of Carboniferous Brachiopoda is noted, and there are also affinities with the Australian Carboniferous fauna.

IN the form of "Appendix No. 2" for 1900 to the *Kew Bulletin*, we have the usual list of new species of plants brought into cultivation for the first time during last year, or re-introduced after having been lost from cultivation.

THREE of the photographs in natural colours, taken by Mr. H. J. Mackinder in his journey to the summit of Mount Kenya, are reproduced by a three-colour process in the May number of the *Geographical Journal*. Colour photography has thus been brought into the service of geographical exploration, and we may expect to see further developments of its use.

THE May number of the *Journal* of the Chemical Society, which now appears with a regularity worthy of emulation by the publications of other scientific societies, contains Sir Henry Roscoe's memorial lecture on Bunsen, accompanied by a photogravure of the lamented chemist, and Prof. Thorpe's presidential address on some characteristics of the study and progress of chemistry in Great Britain during the present century.

THE current number of *The Builder* (May 5) contains reproductions of Mr. Aston Webb's drawings of the proposed buildings to be erected in the Imperial Institute Road, South Kensington, to accommodate the physics and chemistry departments of the Royal College of Science. The original drawings are on view at the Royal Academy.

THE "Statesman's Year-book," edited by Dr. J. Scott Keltie, with the assistance of Mr. I. P. A. Renwick (Macmillan), has been accepted as a trustworthy authority upon all matters of political geography for so many years, that people familiar with its pages, and therefore conscious of the extent and accuracy of the information contained in them, regard it as one of the few essential annuals. The volume for 1900, which has just been published, is larger than any previous edition, and the numerous rearrangements of territories which were made last year have necessitated many changes in the text, several of the sections having been almost rewritten. Four specially prepared coloured maps are included, dealing with (1) the partition of North-east Africa; (2) the reorganisation of British Nigeria and the French West African territories; (3) the political partition of the Pacific; (4) the final arrangement of the boundary between British Guiana and Venezula. The "Year-book" is thus an epitome of recent geographical events as well as a manual of statistical and historical information concerning the states of the world. So long as the volume is kept so completely up to date as it is at present, it is not likely to be superseded.

IN a short note in the current number of the *Berichte*, Dr. Marckwald discusses some peculiarities shown by picric acid and its solutions, in the light of the ionic hypothesis. Picric acid, as usually obtained, has an intense yellow colour, but on recrystallising from strong hydrochloric acid it becomes nearly colourless. If this white crystalline mass is sucked nearly dry at the filter pump and washed with a little water to remove the adhering hydrochloric acid, the yellow colour at once returns. The mother liquor, which at first has only a pale yellow colour, also becomes more intensely coloured as water is added. Dr. Marckwald shows that if it be assumed that picric acid is itself colourless, but that the ions, $C_6H_2(NO_2)_3O$, are coloured, all these somewhat perplexing phenomena find an immediate explanation in terms of the theory of electrolytic dissociation.

THE confirmation of the relations deducible by thermodynamics as existing between the freezing-point and vapour pressures of a very dilute solution, although of considerable importance for the electrolytic theory of solution, presents great experimental difficulties, especially as regards the vapour pressure determinations. An ingenious method attacking this problem is described in the current *Zeitschrift für physikalische Chemie*, by Dr. R. Gahl. A measured volume of air is drawn through the solution, such as hydrochloric acid, and this is passed through pure water, the change of electrical conductivity of which is measured. The number of cases in which such a method can be applied is obviously restricted, but the accuracy attainable appears to be of the order of ·001 mm. of mercury.

THE additions to the Zoological Society's Gardens during the past week include a Grys-bok (*Raphiceros melanotis*) from South Africa, a Yellow-whiskered Lemur (*Lemur xanthomystax*) from Madagascar, presented by Mr. J. E. Matcham; a Violet-necked Lory (*Eos riciniata*) from Molluccas, presented by Mr. H. R. Filliner; two Australian Rails (*Rallus pectoralis*) from New Holland, presented by Mr. C. J. Fox; a Common Boa (*Boa constrictor*) from South America, an Egyptian Eryx (*Eryx jaculus*) from Egypt, presented by Mr. C. W. Lilley; two Eyed Lizards (*Lacerta ocellata*), European, presented respectively by Miss Robinson and Miss Ash; two Edible Frogs (*Rana esculenta*) from Biskra, presented by the Hon. Mrs. A. Cadogan; a Crowned Lemur (*Lemur coronatus*), a Black Lemur (*Lemur macaco*), two Blackish Sternotheres (*Sternothoerus nigricans*), a Radiated Tortoise (*Testudo radiata*) from Madagascar, a Slender Loris (*Loris gracilis*) from Ceylon, two Amherst's Pheasants (*Thaumalea picta*, ♂ ♀), ten Reeve's Terrapins (*Damonia reevesi*), a Three-banded Terrapin (*Cyclemmys trifasciata*) from China, a Grooved Tortoise (*Testudo calcarata*) from Khartoum, too Roofed Terrapins (*Kachuga tectum*), a Hamilton's Terrapin (*Damonia hamiltoni*) from India, a Derbian Sternothere (*Sternothoerus derbianus*), two Black Sternotheres (*Sternothoerus niger*) from West Africa, three Chequered Elaps (*Elaps lemniscatus*) from South America, a Glass Snake (*Ophiosaurus apus*), European; six Kentucky Blind Fish (*Amblyopsis speloea*) from Kentucky, deposited; a Brazilian Tapir (*Tapirus americanus*, ♂) from South America, a Cape Hunting Dog (*Lycaon pictus*, ♀) from South Africa, two Siamese Pheasants (*Euplocamus proelatus*, ♂ ♀) from Siam, two Rufous-tailed Pheasants (*Euplocamus erythropthalmus*, ♂ ♀) from Malacca, purchased; a Crowned Lemur (*Lemur coronatus*), an English Wild Cow (*Bos taurus*), born in the Gardens.

## *OUR ASTRONOMICAL COLUMN.*

COMET GIACOBINI (1900 *a*).—This comet has been in an unfavourable position for observation during the past few weeks, but is now rapidly leaving the sun, and may be searched for in the early morning. The following ephemeris is an abridgment from one given by Herr A. Berberich, of Berlin, in the *Astronomische Nachrichten* (Bd. 152, No. 3636):—

*Ephemeris for 12h. Berlin Mean Time.*

| 1900. | R.A. h. | m. | s. | Decl. ° | ' |
|---|---|---|---|---|---|
| May 21 | 1 | 17 | 22 | +24 | 21·8 |
| 22 | | 16 | 27 | 24 | 41·4 |
| 23 | | 15 | 30 | 25 | 1·2 |
| 24 | | 14 | 31 | 25 | 21·4 |
| 25 | | 13 | 29 | 25 | 41·8 |
| 26 | | 12 | 26 | 26 | 2·6 |
| 27 | | 11 | 21 | 26 | 23·6 |
| 28 | | 10 | 13 | 26 | 44·9 |
| 29 | | 9 | 3 | 27 | 6·5 |
| 30 | | 7 | 50 | 27 | 28·4 |
| 31 | 1 | 6 | 34 | +27 | 50·6 |

At present the comet is moving slowly in a north-westerly direction through the constellation Pisces, almost in a line between $\beta$ Arietes and $\alpha$ Andromedæ.

COLOUR SCREENS FOR REFRACTING TELESCOPES.—The *Astronomische Nachrichten* (Bd. 152, No. 3636) contains a description of some experiments undertaken by Messrs. T. J. J. See and G. H. Peters, at the United States Naval Observatory, to determine the utility of viewing celestial objects through variously coloured screens. It was thought that if a suitable screen was chosen which would cut off the violet light of the secondary spectrum shown by the lens, that a considerable improvement of the definition might be expected, and after trial of several types of light filter, several were found which did materially improve the seeing. The screen specially recommended consists of a solution of picric acid and chloride of copper in alcohol. This is applied in a small cell made to fit as a cap outside the eyepiece of the telescope. It is thought that the method may improve meridan work by furnishing better defined star-discs, and also planetary micrometer measurements on account of the diminution of irradiation.

PHOTOMETRIC REVISION OF HARVARD PHOTOMETRY.—The Harvard Photometry, showing the brightnesses of stars north of declination −30°, and of the sixth magnitude or brighter, was compiled from observations made during the period 1879–82. In 1891, on the return of the photometer to Cambridge from Peru, it was decided to redetermine the magnitudes of these stars, and by the end of 1894 the work was almost completed. Nearly all the observations were made by Prof. E. C. Pickering, the Director of the Observatory of Harvard College, and the results of the revision now form Part i. of the last issue of the *Annals of Harvard College Observatory*, vol. xliv.

## *FITZ GERALD'S "HIGHEST ANDES."*[1]

IN the book entitled "The Highest Andes," Mr. E. A. Fitz Gerald relates the experiences of himself and his party upon the journey which he made in 1896-97 in the neighbourhood of Aconcagua, the highest mountain at present known in South America, which it was his aim to map and to ascend. He describes in considerable detail the various operations of the expedition, and recounts with rare frankness the sensations of himself and of his assistants at low atmospheric pressures. Various other matters of considerable public interest are introduced incidentally in his volume, such as the Trans-Andine Railway and the Boundary dispute between Chili and the Argentine Republic; but the attention of the reader will be mainly engrossed by his history of the attacks upon the two great mountains Aconcagua and Tupungato, neither of which was conquered easily.

Although it is visible from Valparaiso, Aconcagua can scarcely be said to have been known at the beginning of the nineteenth century. Humboldt was certainly unacquainted with its name when he was travelling in Peru. He said many years afterwards that, at that time, Chimborazo was everywhere accounted to be the loftiest mountain in the world. But in his "Aspects of Nature," published in England in 1849, he knew differently, and referred to the Great Andes of Peru and Bolivia which were brought to light by Mr. Pentland; and to Aconcagua, which had been found by the officers of the *Adventure* and *Beagle* on Fitzroy's expedition to be between 23,000 and 24,000 feet in elevation. Since then the mountain has had its ups and downs; or, to employ the language of the geologist, it has had its periods of elevation and subsidence. It got to its lowest level about twenty-seven years ago at a meeting of the Royal Geographical Society. After the reading of a paper by Mr. R. Crawford, C.E., upon a projected railway route across the Andes, Mr. J. W. Miers, another Civil Engineer, got up and said of Aconcagua that "he believed it to be little less than 15,000 feet high. Admiral Fitzroy had described it as being higher than any of the Himalayan peaks; but he must have been mistaken in his calculations, no doubt in conseqence of the difficulty in getting a suitable base for a trigonometrical measurement. He (Mr. Miers) had often seen it void of snow, and as the snow-line in that latitude is about 15,000 feet, *it is manifest that the mountain cannot much exceed that height.*" Though Sir Clements Markham (the present President of the Royal Geographical Society) was at the meeting, it does not appear that either he or any one else entered a protest against this startling statement (see *Proc.* R. Geog. Soc., December 9, 1872, pp. 66-7). Subsequently, Aconcagua rose to a height exceeding 24,000 feet in the pages of the *Daily Chronicle* (January 18, 1897), and it has now, according to Mr. Fitz Gerald, dropped to 23,080 feet, or to almost exactly the height assigned to it by Admiral Fitzroy. This appears to be the greatest elevation that any one has hitherto reached upon a mountain.

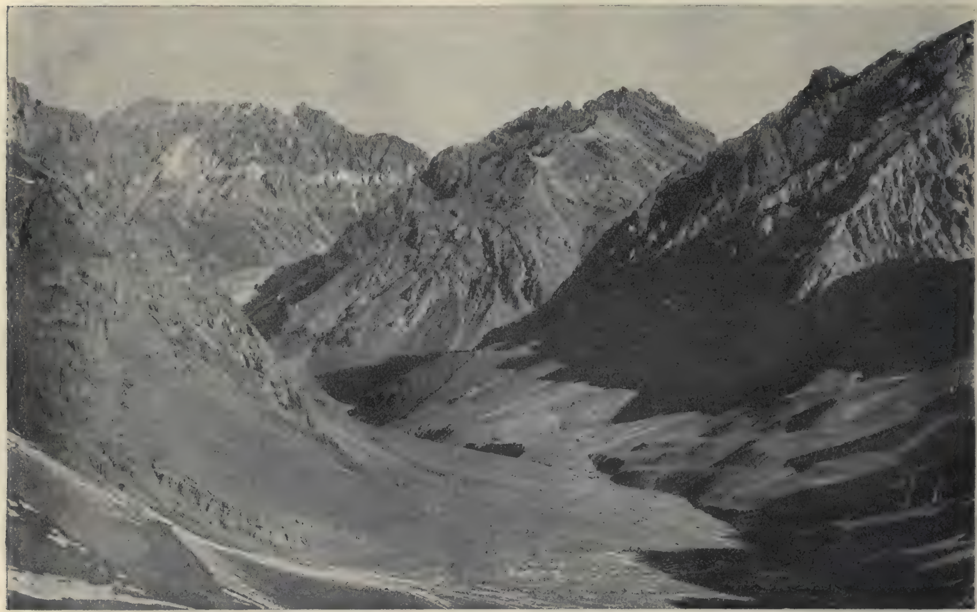

FIG. 1.—Looking down Horcones Valley from glacier.

Mr. Fitz Gerald's Expedition sailed from Southampton on October 15, 1896; left Buenos Aires November 29; and on December 7 arrived at Punta de las Vacas (7858 feet), the terminal station in Argentina of the Trans-Andine Railway.[1] This terminus is only a little more than twenty miles to the south-east of the summit of Aconcagua. No other mountain in the world of anything like its magnitude is approached so closely by railway.[2] An abortive attempt to get to it was first of all made *via* the Vacas Valley, which runs a little west of north from the Terminus and leads to the eastern side of the mountain; and it was subsequently found that the true way towards the summit was by the Horcones Valley, the upper part of which lies to the *west* of the main peak. After some preliminary exploration, a camp was established at the head of this valley, at a height of about 14,000 feet. "The lack of pasturage," it is said, "made it impossible to take the mules any farther," and thenceforward all transport had to effected by men.

---

[1] "The Highest Andes: a Record of the First Ascent of Aconcagua and Tupungato in Argentina, and the Exploration of the Surrounding Valleys." By E. A. Fitz Gerald. 8vo, pp. 390. (London: Methuen and Co., 1899.)

[1] This line is intended to connect Buenos Aires and Valparaiso. Its construction has been suspended for several years, but it has been quite recently stated that progress will shortly be resumed. About 44 miles remain to be made.

[2] The railway which is being constructed towards Chamonix terminates at present at the village le Fayet, which is less than *ten* miles distant from the summit of Mont Blanc. The summit of Mont Blanc is 13,875 feet above le Fayet, and that of Aconcagua is 16,222 feet above Punta de las Vacas.

Besides Mr. Fitz Gerald, the Expedition at this time consisted of Messrs. Vines, de Trafford and Gosse; Zurbriggen, the brothers Joseph and Louis Pollinger, Lanti and Weibel. Matthias Zurbriggen, who was born in Switzerland and lives in Italy, is termed guide, and the rest of the men are called porters; although the two Pollingers and Lochmatter are actually guides, and amongst the best of the younger ones of the Zermatt district. Lanti, who is also called a porter, appears to have been a miner. Mr. Lightbody, an engineer of the Trans-Andine Railway, joined the party at a later date.

On the first day (December 23), Fitz Gerald and Zurbriggen, with four porters and twelve horses or mules, started from the mouth of the Horcones Valley (8948 feet), and went to the spot at its head that has been already mentioned, which was about 14,000 feet above the sea; and, leaving the animals there, some of the party pushed on, with the view of arriving at a depression upon the ridge which leads from the summit towards the north-west; but when an altitude of 16,000 feet is supposed to have been reached, a halt was called on account of the lateness of the hour. "Being much fatigued, we decided not to pitch our tent, but simply to crawl into our sleeping-bags. No one had the energy even to make for himself a smooth place. . . . During the night, one of my Swiss porters, a tall, powerfully-built man, Lochmatter by name, fell ill. He suffered terribly from nausea and faintness." Next day they progressed upwards, but still did not reach the spot for which they were aiming, and passed the night at some elevation that is not mentioned. It was now Mr. Fitz Gerald's turn to feel the effects of diminution in atmospheric pressure.

"I had suffered acutely," he says, "during the afternoon from nausea, and from inability to catch my breath, my throat having become dry from continual breathing through my mouth. . . I was unable to sleep at all, partly because of the difficulty I had in breathing, and partly on account of the dreadful snoring of the men. They would begin breathing heavily, and continue on in an ascending scale till they almost choked. This would usually wake them up, and they were quiet for ten minutes or so, till gradually the whole performance recommenced" (pp. 55-6).

On the following day (December 25) they continued the ascent; and, although the distance that they mounted was small, the effects became more marked. Mr. Fitz Gerald says of himself and also of Zurbriggen: "We were feeling distinctly weak about the knees, and were obliged to pause every dozen steps or so to catch our breath, and frequently we sat down for about ten minutes to recover" (p. 56). On the next night they encamped on the desired spot, which is said to have been 18,700 feet above the sea. During the day, Zurbriggen advanced (according to his estimate, 2000 feet above the camp), and returned "late in the evening, completely exhausted." On the 27th Mr. Fitz Gerald and the rest retreated to 12,000 feet in the Horcones Valley, in doing which, it seems to me, they made a mistake, and sacrificed some of the advantages which had been gained by considerable labour.

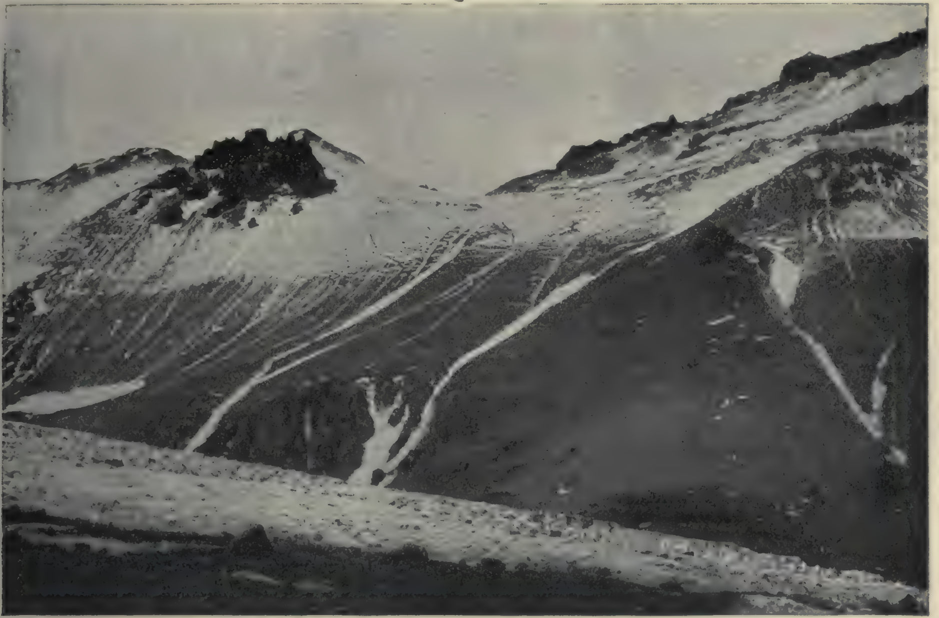

FIG. 2.—Saddle on which the 18,700 ft. camp was situated.

On December 30 they re-started, reached the 18,700 feet camp at the end of the day, and left at 5.45 the next morning with the view of reaching the summit. "At that time we little knew what lay before us; the summit looked so very near that we even talked of five or six hours as a possible time in which to reach it. We set out towards our peak over the loose, crumbling rocks that covered the north-west face; the steepness was too great for a direct line of march, and we were obliged to twist and zigzag."

"I noticed Zurbriggen was going very fast; I was obliged to call to him several times, and ask him to wait for me, as I did not wish to exhaust myself by pressing the pace so early. I was surprised at his hurrying in this way, as it is generally Zurbriggen who urges me to go slowly at first. However, I soon discovered the reason for this; he was suffering bitterly from cold. Seeing that his face was very white, I asked him if he felt quite well. He answered that he felt perfectly well, but that he was so cold he had no sensation whatever left in his feet; for a few moments he tried dancing about, and kicking his feet against the rocks, to get back his circulation. I began to get alarmed, for frozen feet are one of the greatest dangers one has to contend against in Alpine climbing. The porters who had been lagging behind now came up to us; I at once told Zurbriggen to take his boots off, and we all set to work to rub his feet. To my horror I discovered that the circulation had practically stopped. We continued working hard upon him, but he said that he felt nothing. We took off his stockings, and tried rubbing first with snow and then with brandy; we were getting more and more alarmed, and were even beginning to fear that the case might be hopeless, and might even necessitate amputation. At last we observed that his face was becoming pallid, and slowly and gradually he began to feel a little pain. We hailed this sign with joy, for it meant, of course, that vitality was returning to the injured parts, and we renewed our efforts; the pain now came on more and more severely; he writhed and shrieked and begged us to stop, as he was well-nigh maddened with suffering. Knowing, however, that this treatment was the one hope for him, we continued to rub, in spite of his cries, literally holding him down, for the pain was getting so great that he could no longer control himself, and tried to fight us off. The sun now rose over the brow of the mountain, and the air became slightly warm; I gave him a strong dose of brandy, and after a great deal of trouble induced him to stand up. We slipped on his boots without lacing them, and supporting him between two of us, we began slowly to get him down the mountain side. At intervals we stopped to repeat the rubbing operation, he expostulating with us vainly the while. After about an hour and a half, we succeeded in getting him back to our tent, where he threw himself down, and begged to be allowed to go to sleep. We would not permit this, however, and taking off his boots again we continued the rubbing operations, during which he shouted in agony, cursing us volubly in some seven different languages. We then prepared some very hot soup, and made him drink it, wrapping him up warmly in all the blankets we could find and letting him sleep in the sun. In the afternoon he seemed quite right again, and was able to walk about a little" (pp. 61–2).

This episode brought that day's attempt to an end, but the next morning (January 1) they started again at 8 a.m., with temperature at 26° F., passed the place where they had turned back on December 31, and then encountered great and steep slopes of loose, rolling stones; which, so far as the mountain itself was concerned, seem to have formed the greatest difficulty on the ascent. "The first few steps we took caused us to pause and look at one another with dismay. Every step we made, we slipped back, sometimes the whole way, sometimes more. . . . We continued plodding on for some time, our breath getting shorter and shorter as we struggled and fought with the rolling stones in our desperate attempts not to lose the steps we gained. . . . There was nothing to fix our attention upon except the terrible, loose, round stones, that kept rolling, rolling as if to engulf us." Now another one became ill. "Louis Pollinger" (who is an unusually sturdy and powerful young fellow) "was turning a sickly, greenish hue. All the colour had left his lips, and he began to complain of sickness and dizziness." They went on until 2.15 p.m., and then turned back. "Zurbriggen, I think, could have gone a little farther, but even he admitted that he did not think he would be capable of reaching the summit. . . . The temperature had now dropped to 17° F., and the sun gave us no warmth to speak of. Coming down was almost worse than going up. Fatigued as we were, and chilled and numb to the bone, we constantly fell down, and it was four o'clock before we reached our encampment. . . . We were all of us suffering from splitting headaches."

Although Mr. Fitz Gerald speaks frequently of heat and cold, he does not often quote actual temperatures; but at this point he remarks that the temperature fell to 5° F. during the night, that the maximum in the sun had only been 47° F. during the previous three days, and that it had barely reached 29° F. in the shade. Though the cold which was experienced was not at all lower than might have been expected, they found it trying. "The cold at this altitude seems absolutely unendurable after sunset. I have seen the men actually sit down and cry like children, so discouraged were they by this intense cold" (p. 57); and he says, truly, at another place, that "with the barometer standing at fifteen inches, the rarefied atmosphere lowers all the vital organs to such an extent that 20° of frost feels more like 60°" below freezing-point (p. 63). There were four of them in their miserable little tent, packed so close that each time one turned over he was obliged to wake the rest." "A terrible and stunning depression had taken hold upon us all, and none of us cared even to speak. At times I felt almost as if I should go out of my mind. . . . All ambition to accomplish anything had left us, and our one desire was to get down to our lower camp, and breathe once more like human beings" (p. 67); and so down they went, this time to Puente del Inca, 8948 feet, at the mouth of the Horcones Valley, and waited there a week.

On January 9 they started again, passed that night half-way up the Horcones Valley, and on the next day went up to the 18,700 feet camp, ascending from 14,000 feet at the rate of 854 feet per hour! "We all seemed so well that I thought it better not to make an attempt on the mountain next day, but to see what a few days of rest and good food would do for us. My hope was that the system would accustom itself to the rarefied air." The minimum of that night was 1° F., which is the lowest temperature recorded in the volume. At 9 a.m. on January 12, Mr. Fitz Gerald set out once more for the summit, accompanied by Zurbriggen and Joseph Pollinger. "For my own part I knew, after the first quarter of an hour, that the attempt would be fruitless. However, I pushed along, hoping against hope that by some chance I might feel better as we went on. I had barely reached 20,000 feet, when I was obliged to throw myself on the ground, overcome by acute pains and nausea," and he returned to the tent, while Zurbriggen pushed on alone. He did not, however, reach the summit; and, when he was returning, was watched through a field-glass.

"He was apparently quite exhausted; he could only take a few steps at a time, and then seemed to stumble forward helplessly. We watched him thus slowly descend for about an hour and a half; first he sat down for four or five minutes, then he slowly plodded onward again. At last he reached a large patch of snow, where, by sliding, he was able to make better time. He did not reach the tent till after sunset, and then he was speechless with thirst and fatigue" (p. 78).

On January 13, another attempt gave a similar result; but at night preparations were made for a renewed assault on the morrow; and on the 14th, Zurbriggen, Joseph Pollinger, Lanti and Mr. Fitz Gerald started at 7 a.m., "all in excellent spirits—so far as it is possible to be cheerful at 19,000 feet." Things went well until 12 30, when they had reached an elevation which was estimated to be about 22,000 feet, and then Mr. Fitz Gerald collapsed. It is to the credit of the head of the Expedition that he writes so frankly, and one cannot but regret that his perseverance did not meet with success. This is his own description:

"I got up, and tried once more to go on, but I was only able to advance from two to three steps at a time, and then I had to stop, panting for breath, my struggles alternating with violent fits of nausea. At times I would fall down, and each time had greater difficulty in rising; black specks swam across my sight; I was like one walking in a dream, so dizzy and sick that the whole mountain seemed whirling round with me. The time went on; it was growing late, and I had now got into such a helpless condition that I was no longer able to raise myself, but had to call on Lanti to help me. . . . Lanti was in good condition, and could, I feel sure, have reached the summit. He was one of the strongest men we had with us. For a long time past he had been begging me to turn back, assuring me that our progress was so slow, that even should I keep it up I could not reach the top before sunset. I was right under the great wall of the peak, and not more than a few hundred yards from the great couloir that leads up between the two summits. I do not know the exact height of this spot, but I judge it to be about a thousand feet below the top. Here I gave up the fight and started to go down.

"I shall never forget the descent that followed. I was so weak that my legs seemed to fold up under me at every step, and I kept falling forward and cutting myself on the shattered stones that covered the sides of the mountain. I do not know how long I crawled in this miserable plight, steering for a big patch of snow that lay in a sheltered spot, but I should imagine that it was about an hour and a half. On reaching the snow I lay down, and finally rolled down a great portion of the mountain side. As I got lower my strength revived, and the nausea that I had been suffering from so acutely disappeared, leaving me with a splitting headache. Soon after five o'clock I reached our tent. My headache was now so bad that it was with great difficulty I could see at all.

"Zurbriggen arrived at the tent about an hour and a half later. He had succeeded in gaining the summit, and had planted an ice-axe there; but he was so weak and tired that he could scarcely talk, and lay almost stupefied by fatigue. Though naturally and justifiably elated by his triumph, at that moment he did not seem to care what happened to him. At night, in fact, all hope and ambition seemed to depart, after four days spent at this height, and that night we got little sleep, every one making extraordinary noises during his short snatches of unconsciousness—struggling, panting, and choking for breath, until at last obliged to wake up and moisten his throat with a drop of water" (pp. 82–3).

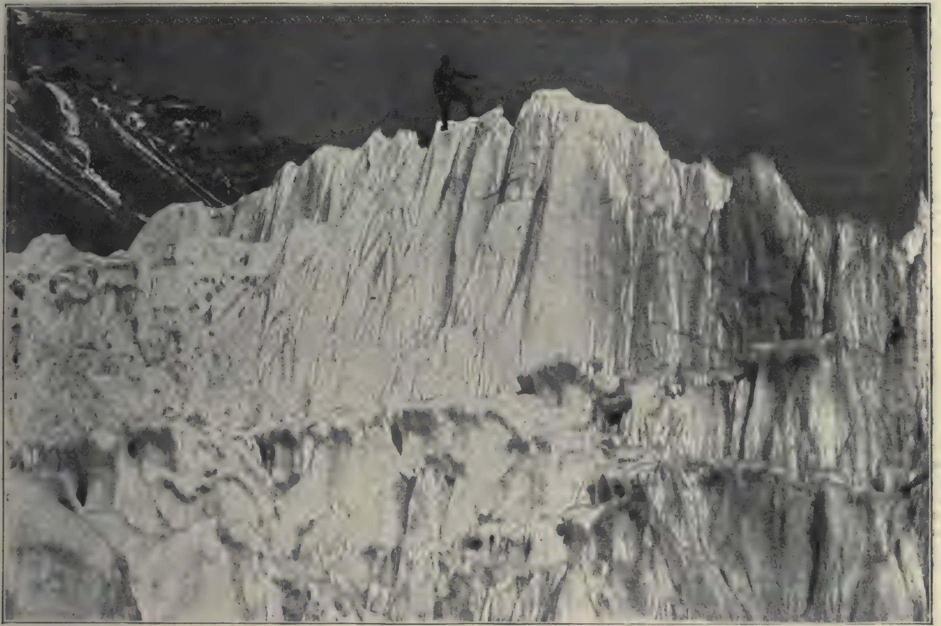

FIG. 3.—Seracs of the Horcones Glacier.

Thus, Zurbriggen alone reached the highest point in the world which has hitherto been ascended; and it is not the least curious fact in this interesting journey that he should have done so, for he was not the most nimble of the party, and in appearance and gait is not the one who might have been expected to be the most successful. That he did succeed was proved on the following 13th of February, when Mr. Vines and Lanti again ascended the mountain, and found an ice-axe on the summit and a substantial pyramid of stones which he had built. The cairn might have been erected by any one, but the axe could have been put there only by himself.

The position assigned to Aconcagua on the map which accompanies Mr. Fitz Gerald's volume is long. 69° 59′ west of Greenwich, 32° 39′ south latitude, and Tupungato is placed about 57 miles to its south. This latter mountain was ascended by Mr. Vines and Zurbriggen on April 12, 1897, but only after three attempts which ended in failure. Upon it, as on Aconcagua, all those who got to considerable elevations were strongly affected by the diminution in the atmospheric pressure which they experienced, and they were sometimes rendered almost incapable. Upon the map, Tupungato is credited with a height of 21,550 feet, but I have not been able to find in the volume the data from which this elevation has been derived. If it has no better foundation than readings of an aneroid barometer, it is probable that the height has been considerably over-estimated. The elevation assigned to Aconcagua is obtained from the railway-levels as far as the terminus at Punta de las Vacas (7858 feet), carried on by levelling and triangulation up the Horcones Valley, and may be considered authoritative. Notwithstanding its great height, the mountain bears little snow in the middle of the summer; and in this respect the observations by Mr. Miers which are quoted at the beginning of this article are supported. Mr. Fitz Gerald, indeed, says that "when Zurbriggen made the ascent of Aconcagua, he went to the summit of the mountain without placing his foot upon snow; the side of the mountain was bare to the top on the north-west slopes" (p 34). The apex of Tupungato was also bare rock. From the absence of great snow-fields and large glaciers in this elevated region, it would appear that the annual snow-fall there is inconsiderable.

Mr. Fitz Gerald's book will give abundant food for reflection to those who think that the loftiest mountains in the world can be scaled, and scaled easily. He confirms the observations of others, that the greatest heights are reached painfully and laboriously, and that there is a pretty constant diminution in pace the higher one ascends. The illustrations in the volume are reproductions of photographs, and out of the forty-five views of scenery which are given, thirty-three are by Mr. Lightbody. The appendix contains notices of the rocks, by Prof. T. G. Bonney; of the reptiles, scorpions and spiders, by Messrs. Boulenger and Pocock; and of the plants, by Mr. Burkill. The collections seem meagre, and nothing except a few rock specimens appears to have been brought from the greatest heights.

EDWARD WHYMPER.

## POTTERY AND PLUMBISM.

DR. T. E. THORPE, F.R.S., gave a lecture on Friday evening, May 4, at the Royal Institution, on the results of an experimental inquiry which he has made, at the instance of the Home Office, on the hygienic questions involved in the use of lead compounds in the manufacture of pottery.

After explaining how lead poisoning occurs in connection with pottery manufacture, he described the conditions which a perfect glaze must fulfil, and named the various forms in which lead compounds enter into the composition of the glazing material as ordinarily employed. He pointed out that experience amply demonstrated, both in this country and on the Continent, that "raw" lead is more generally mischievous in its action than "fritted" lead, that is, lead in the form of a complex silicate associated with alumina, lime, &c. This depends on the more ready solubility of the various modifications of raw lead in the animal secretions, and more particularly in the gastric juice. This fact, indeed, is now generally recognised, and in the inquiry which was instituted by the Home Office in 1893, manufacturers whose names deservedly carry authority in the pottery districts strongly urged the substitution of fritted lead for raw lead in all glazes. Unfortunately, however, this recommendation was not enforced. This may have been due, partly at least, to the circumstance that cases of plumbism occurred from time to time in works where fritted lead was exclusively used. The fact is there is fritted lead and fritted lead.

Dr. Thorpe then proceeded to explain the results of a recent inquiry into the conditions which determine the ease with which lead may be dissolved out from a fritt by dilute acids such as are present in gastric juice. In the first place, it was found that, speaking generally, English fritts yielded a far larger amount of lead to solvents than those made in Holland, Belgium, Germany or Sweden. Indeed, some English specimens of fritted lead were found to be hardly less soluble than raw lead, as shown by the following numbers:—

| | | Lead oxide dissolved, expressed as percentage of total lead oxide present. |
|---|---|---|
| Lead silicate, Specimen I. | | 99·6 |
| ,, ,, ,, II. | | 99·6 |
| Glaze A, made with lead silicate | | 99·2 |
| ,, B, ,, ,, ,, | | 99·2 |
| Various forms of "raw" lead | Litharge | 100·0 |
| | Red lead | 100·0 |
| | White lead | 100·0 |

Next, the inquiry showed that there was no necessary relation between the amount of lead oxide in a fritt and the extent to which it would yield lead to solvents comparable, as regards their action, with animal secretions. Some of the compounds richest in lead were, in fact, among those least attacked by solvents. This is illustrated by the following series of numbers:—

I. *Solubilities practically the same, amounts of lead oxide in the fritt very different.*

| | Percentage of lead oxide in fritt. | Solubility per cent. on fritt. |
|---|---|---|
| Dutch fritt | 18·0 | traces |
| English fritt, A | 40·4 | 0·2 |
| Belgian fritt | 22·4 | 0·7 |
| English fritt, B | 41·3 | 0·7 |
| ,, ,, C | 52·3 | 0·4 |

II. *Solubilities very different, amounts of lead oxide in fritt practically the same.*

| | | |
|---|---|---|
| English fritt, D | 37·9 | 28·0 |
| ,, ,, E | 36·2 | 1·4 |
| ,, ,, F | 45·8 | 10·8 |
| Swedish fritt | 44·1 | 2·1 |

Further inquiry elicited the fact that the extent to which the fritt gave up lead to the solvent depended upon two conditions:—

(1) The existence of a definite numerical relation between the basic and acidic oxides in the fritt, and

(2) Complete chemical union.

The definite numerical relation thus alluded to may be stated in the following terms:—If the sum of the equivalent percentages of basic oxides, expressed as lead oxide, is not more than double the sum of the equivalent percentages of acidic oxides, expressed as silica, the solubility of the fritt, as regards lead, is rarely more than 2 per cent. Any increase in this ratio is attended by an increase in the amount of lead dissolved, and the amount of soluble lead increases very rapidly with even a slight increase in the ratio. The following figures serve to illustrate this fact:—

| | Percentage of lead oxide. | Solubility per cent. on fritt. | Ratio. |
|---|---|---|---|
| Dutch fritt, No. 1 | 18·0 | traces | 1·34 |
| Belgian fritt, No. 1 | 21·8 | ,, | 1·44 |
| Dutch fritt, No. 2 | 19·0 | 1·2 | 1·50 |
| Belgian fritt, No. 2 | 22·4 | 0·7 | 1·52 |
| Swedish fritt | 44·1 | 2·1 | 1·56 |
| English fritt | 24·0 | 0·2 | 1·57 |
| ,, ,, | 40·4 | 0·2 | 1·68 |
| ,, ,, | 24·5 | 0·6 | 1·70 |
| ,, ,, | 36·2 | 1·4 | 1·79 |
| ,, ,, | 36·4 | 2·3 | 1·87 |
| ,, ,, | 45·8 | 10·8 | 2·61 |
| ,, ,, | 37·9 | 28·0 | 2·92 |
| ,, ,, | 70·4 | 67·3 | 3·26 |

It was further found that, provided the ratio of acids to bases is below 2, the nature of the basic oxides has little or no effect upon the amount of the lead oxide dissolved. This may be illustrated by the following numbers:—

| | Lead oxide. | Alumina. | Lime. | Alkalis. | Solubility per cent. on fritt. |
|---|---|---|---|---|---|
| Dutch fritt | 19·0 | 8·1 | 9·0 | 4·9 | 1·2 |
| English fritt | 16·2 | 10·3 | 8·5 | 9·2 | 1·7 |
| Swedish fritt | 44·1 | 5·5 | 0·9 | 3·4 | 2·1 |

Further evidence of the fact that the insolubility of a complex silicate is determined by the ratio of acids to bases, and is independent of the specific nature of the bases, is afforded by the case of flint glass, which consists essentially of a silicate of alkali united with a silicate of lead. Separately, these silicates are readily attacked by dilute acids. When united, as in flint glass, the compound is only very sparingly soluble. Merely to flux together the ingredients of a fritt, with no regard to its composition as a definite chemical compound, and with no regard to the time or temperature needed to complete the chemical changes, is not the proper way to make a fritt.

In the course of the inquiry it was found that the Continental fritts, which conformed to the above ratio, and were distinguished by their comparative solubility, were very difficult to break up by the action of acids, and yielded only minute portions of soluble matter (much of which, however, consisted of lead) to solvents, whereas the English fritts were, for the most part, very easily decomposed by the same treatment, and gave up the greater part of their lead to solution. This led to the surmise that the Continental fritts consisted, in the main, of comparatively stable chemical compounds, the minute quantity of lead dissolved being due to some lead compound—oxide or silicate—in a state of incomplete chemical union. Experiment showed that this surmise was correct. By treating a fritt, compounded so as to be within the limiting ratio, with dilute acid, by far the greater portion of the soluble or incompletely fixed lead may be removed, and a highly insoluble complex lead silicate is obtained. A fritt, for example, containing upwards of 53 per cent. of oxide of lead, and of which the limiting ratio of acids and bases was about 2, had this ratio lowered to 1·8 and the solubility diminished from 2 per cent. to four-tenths of a per cent., the amount of lead oxide in the product so treated being upwards of 52 per cent.

A number of manufacturers and professional fritt makers, acting in conformity with the suggestions which have been put forward, and in response to the invitation of the Home Secretary to have their glazes tested in the Government Laboratory, are now producing lead fritts having a solubility which is even below the standard provisionally suggested in the Home Office Circular of December last.

Although measures based upon the above facts will no doubt largely minimise the evil of lead poisoning, Dr. Thorpe stated that he was not sufficiently sanguine to suppose that they would altogether stamp out plumbism in the Potteries. It must be clearly understood that complete immunity from lead poisoning can never be obtained so long as lead compounds continue to be used. The true solution is to be found in the more general adoption of leadless glazes. That leadless glazes of a high brilliancy, covering power and durability, and adapted to all kinds of table, domestic and sanitary ware, to china furniture, to tiles, insulators and electric fittings of the most varied kind, are perfectly practicable, was illustrated by reference to the numerous examples of leadless glazed ware which, thanks to the liberality of a number of the manufacturers, were exhibited to the audience. Among them were specimens from Mintons, from the Worcester Royal Porcelain Company, Burgess and Leigh, Barker and Read, Bernard Moore, the Crystal Glaze Company, Hawley Brothers, Defries, and others. Telegraph insulators of Doulton's and Buller's make were exhibited by the Post Office.

Dr. Thorpe stated that leadless glazed ware was now being supplied to a number of the Government Departments and to certain of the London Clubs. He further stated that the London School Board had resolved to insert a clause in all specifications for new works strictly prohibiting the use of any pottery goods involving lead glaze wherever practicable.

The fact that the application of leadless glazes has passed beyond the experimental stage is so obvious that the Secretary of State now proposes to relax the Special Rules, issued by the Factory Department, in regard to the pottery industry in the case of factories or processes in which no compounds of lead are used.

Dr. Thorpe concluded by remarking that every intelligent potter must concede that there is an ample field for investigation by modern methods of attack into problems connected even with the first principles of his art. The craft of the potter largely depends upon the intelligent application of scientific principles. Whether, however, modern science enters into it to the extent that might be desired is perhaps open to question.

There is probably no industry in the world, certainly none in England, so conservative in its operations as that of the potter. The best of English earthenware still enjoys, no doubt, the pre-eminence which the skill and aptitude of Wedgwood and his immediate followers imparted to it. The great potter was fully abreast of the physical science of his day, and was quick to test or take advantage of any discovery which seemed to promise to be of service to his art. But perhaps it may be doubted whether the spirit of Wedgwood actuates his successors to the extent that might be desired. It is at least certain that the exercise of this spirit, that is, the intelligent application of simple chemical principles, would years ago have obviated, to a large extent at least, this evil of plumbism among the pottery workers.

## *APPLICATIONS OF ELECTRICAL SCIENCE.*[1]

I FEEL very much honoured by having been placed in the position I now occupy, and by having to deliver this opening address to the Dublin Branch of the Institution of Electrical Engineers. I believe that we are one of the first branches that has developed into the meeting stage of our existence, and may congratulate ourselves on having passed through our larval transformations safely and rapidly, and on our having been the first to emerge into an imago.

The action of the parent Institution in founding these local branches is worthy of our grateful commendation. We are left perfectly free to develop our own life untrammelled by any rules except such as we would ourselves have necessarily chosen to govern our actions. We have the great advantage of being a branch of a most distinguished Institution of world-wide reputation, and that without paying any extra subscription. I hope that we will add to the life and work of that Institution, and thereby promote both our own interests and the welfare of mankind. Papers and discussions here will be taken as delivered to the Institution of Electrical Engineers, and, if of sufficient merit, will be published in its *Proceedings*, thus securing to us a world-wide publication, while at the same time ensuring that Ireland is credited with the work done.

The history of electricity in the nineteenth century is far too large a subject for an occasion like the present one, but certain aspects of this history convey valuable lessons for the future and may well engage our attention in this last year of the century, and may help us to lay the foundations for further advance in the next. The aspect of the history of electricity during the nineteenth century to which I desire to direct your attention is an object-lesson of how to apply science to further the well-being of mankind. The history of any applied science might be considered in this aspect, but the history of applied electricity is particularly appropriate for being thus considered, for several reasons. The history is condensed within a few years; the discoveries of science have followed one another with extraordinary rapidity, and within a few years after the discoveries were made they have been applied to the use of man. It is just a hundred years since Volta discovered how to make continuous electric currents. Within a few years of that discovery their chemical actions were discovered and electric lights produced, both arc and incandescent. Twenty years afterwards the magnetic effect of an electric current was discovered by Œrsted, its mathematical theory evolved by Ampère, and the law of its intensity worked out by Ohm. Some fifteen years afterwards, Faraday discovered how to produce electric currents by magnetism. Immediately after the discovery of the principle of the conservation of energy it was applied to electro-magnetism, and the foundation of our whole system of electro-magnetic measurement was laid. Faraday's belief in the correlation of electricity and light, following lines suggested by Lord Kelvin, was forged into a consistent theory by Clerk Maxwell, and this theory confirmed experimentally by Hertz. Such, in brief, is the scientific history of electro-magnetism during the expiring century, and on this science practically all the applications of electricity depend.

I may pause for an instant to consider where this theory now lands us. The all-pervading ether has been realised as the means of transmitting light, electricity and magnetism, and we are looking forward to its properties explaining chemical actions and gravitation. We are still looking for a theory of its structure which will give a dynamical explanation of its properties. We know how to express these properties by quantities we call electric and magnetic force, whose laws we know, but whose laws we are, as yet, unable to explain by any structure working on dynamical principles. So far as we know, the properties of electric and magnetic force are explicable upon dynamical principles; so far there is no known necessity for seeking for adynamical properties in the ether; so far we may hope to explain electro-magnetism upon the dynamical principles of Newton's laws without invoking any other principles than those of force and inertia, as expounded in these laws. Until, however, a satisfactory theory of the nature of the ether has been actually invented, there will remain some doubt as to the adequacy of these fundamental dynamical laws to explain all its properties. The direction in which it is most probable that an explanation will be found is in the hypothesis that the ether is of the nature of a perfect liquid full of the most energetic motion. We know that a gas consists of separate molecules in intensely energetic irregular motion. I expect that the ether is a perfect liquid in intensely energetic irregular motion: much more rapid than that of any gas: with a rapidity of internal motion comparable with the speed of light: maybe with enough energy in each cubic centimetre to keep hundreds of horse-power going for a year, if only we could get at it. So far as this hypothesis has been worked at there seems nothing impossible about it, but, on the contrary, much possibility in it, and, to my mind, its inherent simplicity confers on it a great probability.

Be that as it may, we now know that in the electric lighting of our cities, in electric tramways and railways, in electric furnaces and electrolytic vats, and in the other innumerable applications of electricity, we are harnessing the all-pervading ether to the chariot of human progress, and using the thunderbolt of Jove to advance the material welfare of mankind.

Having thus shortly considered the progress of electrical science, the history of the *applications* of electricity may be thus summarised. Shortly after Œrsted discovered the magnetic effect of an electric current this discovery was applied to telegraphy, and Faraday's discovery of how to generate electric currents by magnetism was almost immediately applied to the same use. Telegraphy developed rapidly, and many subsequent discoveries were due to the observations made in the practical application of electricity to telegraphy. This has been developing ever since, accumulating knowledge and applying the accumulations to produce more knowledge and more applications, till all this has resulted in the perfection of the multiplex telegraph and the wonders of the telephone and wireless telegraphy. No other department of applied electricity has had such a continuous development, hardly any interval elapsing between discovery and application in its case, while in almost every other case years have elapsed between discoveries and their application. It is especially the object of this address to call attention to the cause of this and to the lessons to be learnt from it.

---

[1] Inaugural address to the Dublin Section of the Institution of Electrical Engineers, delivered by Prof. G. F. Fitzgerald, F.R.S. Abridged from the *Journal* of the Institution, April.

Within the first decade of the century, electrolysis and the electric light were discovered; but, except on a small scale in electro-plating, it was reserved for the last quarter of the century to see their application to the general use of mankind. Before her Majesty began to reign, Faraday had discovered how to generate electric currents by magnetic actions; but, except to generate currents to light a couple of lighthouses, no applications of Faraday's discovery to generate electric currents on a large scale was made till Wilde, Gramme and Siemens worked at it, more than thirty years after its discovery. The application of electric currents to transmit power on a small scale was made in the electric telegraph years before any applications were made on a large scale. Except for a few experiments by Jacobi and others, the transmission of power by electric currents on a large scale is the work of the last twenty—one might almost say of the last ten—years.

Consider now what are the characteristics of the applications which developed continuously, and what were those of the applications which lay dormant for years. Maybe we can learn from this consideration how to arrange that, in the future, our discoveries may not lie for years dormant.

The most noticeable difference between the applications of electricity that developed and those that lay dormant is that those that developed were useful on a small scale, while those that lay dormant were not useful until developed on a large scale. Electro-plating and telegraphy were useful on quite a small scale. Experiments as to their efficiency could be conducted on the laboratory scale with quite cheap apparatus, and thus they were actually developed.

A recognised authority, who is fond of poking paradoxical fun at professors, has recently stated that "the progress of telegraphy and telephony owes nothing to the abstract scientific man." I do not know exactly what he means by the abstract scientific man, but I do know that telegraphy owes a great deal to Euclid and other pure geometers, to the Greek and Arabian mathematicians who invented our scale of numeration and algebra, to Galileo and Newton who founded dynamics, to Newton and Leibnitz who invented the calculus, to Volta who discovered the galvanic cell, to Œrsted who discovered the magnetic action of currents, to Ampère who found out the laws of their action, to Ohm who discovered the law of the resistance of wires, to Wheatstone, to Faraday, to Lord Kelvin, to Clerk Maxwell, to Hertz. Without the discoveries, inventions and theories of these abstract scientific men, telegraphy as it now is would be impossible.

We have seen that electro-plating and telegraphy were capable of development on a small scale, and were consequently largely developed by laboratory research. The development of dynamos from Faraday's discovery required expensive experiments, and to test their efficiency on a large scale required very expensive experiments indeed. It was not possible to conduct experiments that would be of much practical use on the small scale on which laboratory experiments have to be conducted, on account of the miserable pittance that is at the command of scientific laboratories. The only opportunity of conducting experiments on a large scale is when an inventor can control capital, as, for example, if he himself is in the position of an engineer to some wealthy body whose money he can employ on experiments. Jacobi and others spent a good deal of money, no doubt, on experiments in power distribution by electro-magnetic engines, but their expenditure, though quite considerable as compared with the usual run of laboratory experiments, was as nothing compared with the enormous sums spent by the pioneers of modern electro-magnetic machinery on *their* experiments.

What we have found, then, is that development depended on whether or no people experimented energetically upon how to render each discovery of practical utility; where experimenting was energetic, development was rapid; where experimenting was not energetic, development was slow. We have further found that the energy of experimenting depended on the money available; where little money was required, development was rapid; but it was slow where large sums of money were required in order to perform valuable experiments.

We may further inquire how it happened that money and time became available for costly experiments. Money is available for laboratory experiments by the beneficence of private and public endowment, and time is available by the devotion of scientific men to the advancement of natural knowledge. These have been available because some few men have had faith in the desirability of knowledge both for its own sake and for the material and moral advantage of mankind. Money has been available in England on a large scale in the past because of the enthusiastic faith of some very few men in the possibilities of scientific discoveries. One of the most remarkable instances of this faith was in the case of the great experiment of laying the Atlantic cable. A few men with strong faith impressed their belief on a few capitalists, and after years of most expensive experimental work they at last brought their great undertaking to a successful issue; the general body of capitalists meanwhile looking on with amused incredulity. The development of the dynamo depended similarly upon the strong faith of individuals, who spent immense sums of money and much time and energy on the subject because they had faith in its possibilities. It is remarkable how many of the developments of scientific discoveries of the latter years of the century have been due to foreigners or firms with foreign leaders, such as Siemens Brothers. This has been largely due to the fact that foreigners are far in advance of us over here in their faith in the possibility of using scientific discoveries. The rapid advance of the applications of science in the last quarter of this century has been very largely due to the growth of this faith. It has grown to a strong conviction in the ordinary public of America and the Continent, and is growing daily stronger over here, but is still far weaker here than in other parts of the civilised world. The result of this has been that while the germs of many of the greatest inventions have been made within the British Isles, we have not been pioneers in any great advance in the applications of electricity since the development of submarine telegraphy. Possibly another cause has been our obstinate retention of our abominable series—one cannot call it system—of weights and measures. It is with great hopefulness that I see public opinion gradually growing in favour of the metric system.

How does it happen that one of the foremost countries in advancing science has been one of the last to appreciate the possibilities of applied science? This has been due partly, no doubt, to our great success as manufacturers and as mere mechanical inventors. No doubt Watt was a truly scientific inventor, and even mere mechanical inventors are appliers of scientific knowledge that was discovered, in the most part, by scientific men centuries ago; but most of our success as manufacturers has been due to mechanical inventions and to our well-trained and expert artisans, and not to the useful application of recent scientific discoveries. This great success, and the absence of scientific training in our schools, and the want of contact between manufacturing and scientific society, have all contributed to prevent a due appreciation of the value of scientific discovery and experiment as a means of advancing the material wealth of society.

When can we expect the country or generous benefactors to learn that science on a large scale is at the basis of the material prosperity of the country, and that science on a large scale is very expensive. Of what use is 200*l*. a year in making experiments on a commercial scale? Ten thousand pounds a year would be more like the figure required; and 10,000*l*. a year could be most profitably spent on experimental work here in Ireland, on the one subject of utilising our bogs. It is most probable that the energy of their combustion could be transmitted to our towns to provide them with light and power; but the preliminary experiments are far beyond the capabilities of a scientific laboratory.

Then there are the questions of three-wire tramways, leaky telegraph lines, submarine relays, sun engines, of flying machines which Lord Rayleigh considers can be constructed if money enough were forthcoming, and of vacuum tubes as a means of illumination, and of numberless other matters already ripe for application, to say nothing of the innumerable scientific discoveries that have not yet been even suggested as having practical applications.

Besides these industrial laboratories, all our Government departments, such as the army and navy, should have large experimental organisations where any invention that promised success would be developed and seriously tried. The decision of what to try should not be left to mere officials, however distinguished, but should be referred to independent scientific advisers—persons who were not trammelled by official traditions, but were in touch with scientific advance and enthusiastic believers in it. If the country spent a couple of millions per annum on experimental work of this kind it would bear much fruit, and we should not find ourselves out-shot by semi-barbarous farmers.

Hope is the great incentive to exertion. Without it a nation is dead. Without it we lose all belief in the possibility of improvement, and improvement at once becomes impossible. The history of electrical engineering, the utilisation of the all-pervading ether for the service of man, should strenghen our hope and our belief in the possibility of improvement. For has it not revolutionised society and enabled high and low, rich and poor, to lead better lives, by making life less hard and grimy, and thus improved the well-being of man both materially and, what is far more important, morally as well?

---

## *UNIVERSITY AND EDUCATIONAL INTELLIGENCE.*

OXFORD.—The following are the principal lectures announced for this term:—Prof. Clifton, practical physics: Mr. Baynes, elementary electricity and magnetism; Mr. Jervis-Smith, dynamo and motor machinery, with electrical testing; Prof. Odling, silicon compounds; Dr. Fisher, metals and organic chemistry; Mr. Watts, organic chemistry; Mr. Marsh, practice of organic chemistry; Mr. Hartridge, aromatic compounds; Mr. Vernon Harcourt, subjects of the preliminary examination; Mr. Elford, the elements treated in the periodic order; Mendeleef's periodic system, Groups vii. and viii.; great chemists and their work; Mr. Walden, synthetical methods in organic chemistry; Mr. Wilderman, equilibrium and velocity of physical and chemical reactions in heterogeneous systems; Prof. Miers, the new theories of crystal structure; Mr. Bowman, the crystallography of optically active substances; Prof. Sollas, history of the earth; Mr. Mackinder, the natural regions of the Old World; Mr. Dickson, the climatic regions of the globe; Mr. Herbertson, mountain types; Prof. Weldon, general course of morphology; variation, inheritance, and natural selection; Mr. Goodrich, annelids; Mr. Jenkinson, vertebrate embryology; Mr. Günther, arthropoda; Mr. Barclay Thompson, mammalian morphology; mammalian palæontology; Prof. Gotch, the central nervous system; Prof. Gotch and Mr. Ramsden, advanced course of physiology; Mr. Mann, advanced histology of nervous system; Mr. Burch, physiological physics; Mr. Mann, practical histology; Prof. Vines, elementary course of botany; Prof. Tylor, early stages of civilisation (arts of subsistence and protection); Sir J. Burdon Sanderson, general pathology; Dr. Ritchie, pathological bacteriology; Dr. Collier, medical diagnosis; Mr. Symonds, fractures and dislocations; Prof. Thomson, vascular and respiratory systems; Mr. Smith Jerome, medical pharmacology and materia medica; Prof. Esson, the synthetic geometry of conics; Prof. Love, hydrostatics and hydronamics; Prof. Elliot, the theory of functions.

Mr. William Hatchett Jackson, science tutor of Keble College, who has been elected to the post of Radcliffe's librarian, vacant by the resignation of Sir Henry Acland, has entered on his duties. The new Radcliffe Library, erected for the University by the Drapers' Company, is meanwhile approaching completion.

Scholarships in natural science are announced by the following colleges:—Merton and New, July 3; Balliol, Christ Church and Trinity, December 4; Magdalen, December 11.

It has been decided that diplomas in geography shall be granted by the University; the details of the scheme have yet to come before Congregation and Convocation.

CAMBRIDGE.—Honorary degrees are to be conferred on the Hon. Edmund Barton, delegate from New South Wales in connection with the Australian Commonwealth Bill, and on H.M. the King of Sweden and Norway.

There are vacancies at the University Tables in the Zoological Stations of Naples and Plymouth. Applicants should write to Prof. Newton before May 24.

It is proposed to affiliate the University of Tasmania. Bachelors of Arts and Bachelors of Science of that University will thereby be entitled to proceed to Cambridge degrees after two years' residence.

The Financial Board estimate that, owing to the loss of fees, &c., consequent on the absence of many members of the University in South Africa, the income of the Chest will next year fall short of the necessary expenditure by 650*l*.

Seventeen additional freshmen were matriculated on May 5.

Mr. Thomas Andrews, F.R.S., has presented to the Chemical Laboratory a valuable echelon spectroscope, for which the special thanks of the University have been ordered.

---

DR. TUNNICLIFFE has been appointed to the chair of materia medica and pharmacology in King's College, London.

DR. JOHN WYLLIE has been elected to succeed the late Sir Thomas Grainger Stewart in the chair of medicine in the University of Edinburgh.

IN order to enable Essex dairy-farmers, and ladies engaged in dairy-work, to gain an insight into the organisation and practice of the agricultural industries of Denmark, the Essex Technical Institution Committee have made arrangements for a party to visit that country. Visits will be made to a number of schools and other institutions, farms, and manufactories concerned with dairying, and a valuable insight will be obtained into Danish methods. Full particulars of the programme can be obtained from Mr. T. S. Dymond, County Technical Laboratories, Chelmsford.

THE growth of municipal technical schools in England during the ten years which followed the passing of the Technical Institution Act, 1889, formed the subject of an inquiry made by the National Association for the Promotion of Technical and Secondary Education a short time ago. The results showed that a capital sum of 2,340,651*l* had been spent on technical schools, and that there were 239 such schools (including agricultural and dairy schools and domestic science schools) in existence or in course of establishment. Since the conclusion of the inquiry, technical schools had been erected, or it had been decided to erect them, in several other towns, and the latest report shows that the total amount incurred for 272 schools under municipal and public bodies is now at least 2,643,172*l*.

THE progress of science and education in the United States is largely due to the interest taken in the work of colleges and universities by private benefactors. Scarcely a week passes without affording instances of generous gifts to institutions of this kind, by persons who desire to promote the development of national character and industries. As an example of this public spirit, we have the case of Dr. D. K. Pearson, of Chicago, who, on attaining his eightieth birthday recently, decided to add 525,000 dollars to the 2,000,000 dollars he had previously given to colleges. Then we have the announcement in *Science* that Mr. Andrew Carnegie has promised the trustees of the Carnegie Institute, Pittsburg, Pa., to become responsible for 3,000,000 dollars, the amount estimated as necessary for the proposed extension and enlargement of the building at the entrance of Schenley Park. The new building will be nearly six times as large as the present one. We should be glad to be able to record many similar gifts to institutions devoted to science and education in this country.

ONE of the good effects of the technical education movement during the past ten years is that many secondary schools, such as grammar and endowed schools, which formerly excluded science from their curricula, have had to adapt themselves to modern requirements as a condition of receiving assistance from technical education authorities. The annual report of the National Association for the promotion of Technical and Secondary Education refers to an inquiry undertaken to determine the extent of the changes which have been brought about in this way, both by the establishment of new secondary schools and by the adaptation of existing secondary schools for the purposes of technical education. The facts revealed by the inquiry go to show that in England alone, since 1889, 81 new public secondary schools have been established, while 215 existing schools have been extended mainly for the purposes of science teaching. As regards the schools in the latter category, the extensions to 195 of them have resulted in the addition of 251 physical and chemical laboratories, 77 workshops for manual training, 76 lecture-rooms, and 50 class-rooms. The total sum of money involved by these developments is 764,449*l*. By their capital grants to secondary schools, County Councils have exerted a direct influence in the reorganisation, and have secured a voice in the management and control of the schools. By the Councils' annual maintenance grants, the work of reorganisation has been gradually consolidated, and the permanence of proper management and control has become assured. It is not surprising, therefore, that the latter, as a continuous source of income to secondary schools, have been increasing in number and in value during recent years.

## *SOCIETIES AND ACADEMIES.*

### LONDON.

**Royal Society,** February 1.—"Researches on Modern Explosives: Second Communication." By W. Macnab, F.I.C., and E. Ristori, Assoc. M.Inst.C.E., F.R.A.S. Communicated by Prof. Ramsay, F.R.S.

The object of the experiments was to endeavour to find a means of determining more accurately than has hitherto been done the temperature reached when an explosive is fired in a closed vessel.

A modification of the method developed by Sir W. C. Roberts-Austen was employed. A thin platinum wire was melted by the heat of the explosion, but a thick wire was unaltered. This showed that the temperature reached was above the melting point of platinum, and also that the duration of the maximum temperature was very short. From this it was argued that if rhodium-platinum couples of different diameters, sufficiently thick not to be melted during explosion, were used in a bomb, the deflections of the galvanometer indicated would vary inversely with the sizes of the wires forming the couples; that in this way data might be obtained from which might be calculated the deflection of an infinitely thin couple, which could be capable of taking up the heat in an infinitely short time, and that this deflection expressed in degrees would represent the actual temperature reached.

Couples formed of wires of pure platinum and platinum alloyed with 10 per cent. of rhodium, varying in diameter from 0·01 to 0·044 of an inch, were employed. Each couple was successively fixed inside the bomb, and on firing the explosive the deflection of a spot of light reflected from the mirror galvanometer was photographically recorded.

These records show the uniformity of the results, and also the time occupied in heating each couple to its maximum, and that the deflections are in inverse order to the thickness of the couple used.

Two series of experiments made with two different explosives —ballistite (composed of 30 per cent. nitroglycerine and 70 per cent. gun-cotton) and gelatinised gun-cotton—were carried out with a number of different couples, and the results expressed as curves show the gradual rise of the deflections as the thickness of the couple diminishes; but all through the gun-cotton curve is below the ballistite curve, thus indicating that the temperature reached during explosion of the gun-cotton is lower than that of the ballistite.

Experiments made with the following explosives showed that the relative temperature can be easily ascertained. Gun-cotton gave the lowest temperature, and in order came cordite, ballistite (composed of 70 per cent. soluble nitro-cotton and 30 per cent. nitroglycerine) and ballistite (composed of 50 per cent. soluble nitro-cotton and 50 per cent. nitroglycerine).

Another series of experiments is in progress for determining the other necessary elements which will be required before the value of these deflections of the galvanometer can be accurately expressed in degrees of temperature.

April 5.—"Über Reihen auf der Convergenzgrenze." Von Emanuel Lasker, Dr. philos. Communicated by Major MacMahon, F.R.S.

**Linnean Society,** April 19.—Dr. A. Günther, F.R.S., President, in the chair.—On behalf of the Hon. Charles Ellis, the President exhibited photographs of a large tree, *Taxodium distichum*, growing at Oaxaca in Mexico, and of another gigantic tree, a native of Cambodia. The circumference of the former, at a height of 3 feet from the ground, was stated to be 143 feet, while the height was estimated to be not more than 100 feet. The native name for this tree is *Sabino*. Mr. Daydon Jackson read an account of it, quoting from Loudon's *Mag. Nat. Hist.* vol. iv. (1831), p. 30, and Humboldt's "Views of Nature," p. 274. The second gigantic tree, which could not be satisfactorily determined from the photograph, had been observed growing on the Makong River, near the celebrated ruins of the great city of Angkorwat in Cambodia.—Messrs. W. B. Hemsley and H. H. W. Pearson read a paper on some collections of high-level plants from Tibet and the Andes. Mr. Hemsley first gave a brief history of the botanical exploration of Tibet, followed by an account of the unpublished collections presented to Kew by Captain Wellby and Lieut. Malcolm, by Captain Deasy and Mr. Arnold Pike, and by Dr. Sven Hedin. These collections were all made at great altitudes in Central and Northern Tibet; few of them below 15,000 feet, and some of them at 19,000 feet and upwards. The highest point at which flowering plants had been found was 19,200 feet above the level of the sea. The plants recorded by Deasy and Pike at altitudes of 19,000 feet and upwards are:—*Corydalis Hendersoni*, *Arenaria Stracheyi*, *Saxifraga parva*, *Sedum Stracheyi*, *Saussurea bracteata*, *Gentiana tenella*, *G. aquatica*, an unnamed species of *Astragalus*, and an unnamed species of *Oxytropis*. These are the greatest altitudes on record for flowering plants. Deep-rooting perennial herbs having a rosette of leaves close to the ground, with the flowers closely nestled in the centre, are characteristic of these altitudes. The predominating natural orders are:—Compositæ, Leguminosæ, Cruciferæ, Ranunculaceæ and Gramineæ. The Compositæ largely predominate, and the genus *Saussurea* is represented by numerous species. Specimens of about a dozen species were shown to illustrate the great diversity exhibited by this genus in foliage and inflorescence. Liliaceæ and the allied orders were very sparingly represented. Two or three species of onion occur; one of them, *Allium Semenovii*, in great abundance up to 17,000 feet. None of the collections contained any species of orchid.—Mr. H. H. W. Pearson described the Andine flora, with special reference to Sir Martin Conway's small collection of plants brought from Illimani in the Bolivian Andes in 1898. In consequence of the labours of d'Orbigny, Pentland, Meyen, Weddell, Mandon and other botanists, the high-level flora of the mountains of Bolivia is better known than that of any other equally elevated region of the Andes. Weddell's collections form the nucleus of the materials from which the "Chloris Andina"—the classic work on the flora of the High Andes—was prepared. Many collectors have obtained plants in various parts of the Andes at elevations stated to be greater than 17,000 feet. Colonel Hall states that he saw four plants on Chimborazo in 1831 at "nearly 18,000 feet." These were two species of *Draba*, one of which was *D. aretoides*, H. B. K., and two Composites, one being a *Culcitium*. Mr. Whymper and others have thrown some doubt upon the determination of this elevation, and it is probable that it was over-estimated. Out of forty-six species of flowering plants obtained by Sir Martin Conway, seven are from 18,000 feet or above it, two being as high as 18,700 feet. These, the highest Andine plants on record, are *Malvastrum flabellatum*, Wedd., and *Deyeuxia glacialis*, Wedd. Thirty-nine species in this collection were found above 14,000 feet; these belong to thirty-four genera and twenty-one natural orders; fifteen (*i.e.* about three-eighths of the collection) are Compositæ. Of the thirty-four genera, one only —*Blumenbachia*—is endemic to South America. The species, with one exception, are confined to the Andes, eight or nine of them not being found outside Bolivia. In the collection made by Mr. Fitzgerald's expedition in the Aconcagua valleys between 8000 and 14,000 feet, ten genera (*i.e.* one quarter of the whole) are endemic in South America. The contrast between this and the small endemic element in the Conway collection from above 14,000 feet gives additional support to the generalisation that the flora of high levels is more cosmopolitan than that of low levels.—A paper was read by Mr. E. S. Salmon on some mosses from China and Japan.

### MANCHESTER.

**Literary and Philosophical Society,** April 24.—Prof. Horace Lamb, F.R.S., President, in the chair.—The following gentlemen were elected honorary members of the Society:—Prof. James Dewar, F.R.S., London; Prof. J. A. Ewing, F.R.S., Cambridge; Prof. A. R. Forsyth, F.R.S., Cambridge; Prof. James Geikie, F.R.S., Edinburgh; Prof. Ernst H. P. A. Haeckel, Jena; Prof. H. A. Lorentz, Leyden; Mr. Robert Ridgeway, Washington, U.S.A.; and Mr. Beauchamp Tower, London. The following were elected officers of the Society for the session 1900–1:—President, Prof. Horace Lamb, F.R.S.; vice-presidents, Prof. O. Reynolds, F.R.S.; Mr. Charles Bailey; Prof. W. Boyd Dawkins, F.R.S., and Mr. J. Cosmo Melvill; hon. secretaries, Mr. Francis Jones and Prof. A. W. Flux; treasurer, Mr. J. J. Ashworth; hon. librarian, Mr. W. E. Hoyle.

### PARIS.

**Academy of Sciences,** April 30.—M. Maurice Lévy in the chair.—On the telescopic planets, by M. C. de Freycinet. The ideas of Laplace upon the distribution of the telescopic planets in concentric spherical layers round the sun are developed analytically and confirmed. If the asteroids are divided into three groups according to their inclination, the mean distance of the planets of these groups from the sun is sensibly constant. —On the transparency of aluminium for the radium radiation, by M. Henri Becquerel. A study of the penetration of thin aluminium sheet by the radium rays, the latter being placed in a strong magnetic field and the effects of the deviable and non-deviable rays being studied separately.—Study of manganous fluoride, by MM. Henri Moissan and Venturi. Pure anhydrous manganous fluoride, $MnF_2$, was obtained in four ways: by the action of a solution of hydrofluoric acid upon metallic manganese, by the interaction of gaseous hydrogen fluoride and the metal, by heating manganese fluosilicate in a current of HF at 1000°, and by dissolving manganese carbonate in the acid. The crystallised $MnF_2$ could not be prepared from aqueous solution, on account of the sparing solubility of the salt in water, but is readily obtainable by fusing a mixture of the salt with manganese chloride.—Agricultural maps of the Canton of Redon. The composition of the soil from the point of view of lime, magnesia, potash and nitrogen, by M. G. Lechartier. An account of the work carried out at the agricultural station of Rennes.—On the vertical trunks, stems and roots of *Cordaites*, by M. Grand'Eury. The view is put forward that *Cordaites*, like *Sigillaria* and other fossil plants dealt with in previous papers, actually grew in the place where they are found, many ligneous trees commonly regarded as growing only on dry land flourishing well with their lower portions constantly submerged in water.—Prof. Suess was nominated a Foreign Associate in the place of the late Sir Edward Frankland.—On a relation between the theory of continuous groups and the differential equations with fixed critical points, by M. Paul Painlevé.—On the function S introduced by M. Appell into the equations of dynamics, by M. A. de Saint Germain.—An improved and simplified solar microscope, by M. A. Deschamps.—The telemicroscope, by M. A. Deschamps.—On an experiment of M. Jaumann, by M. P. Villard. In an experiment described by M. Jaumann, a charged glass rod was brought near a tube immersed in oil, in which kathode rays were being developed, the bundle being repulsed. As these results were not in agreement with the usual hypotheses concerning the kathode, an attempt was made to repeat the experiments, but no deviation of the rays in the opposite direction to that predicted by the theory could be obtained.—On the radium radiation, by M. P. Villard. The rays not deviable in a magnetic field have much greater penetrative power than the deviable rays. The ordinary X-rays from a Crookes' tube behave similarly.—Luminescence of rarefied gases round a metallic wire communicating with one of the poles of an induction coil, by M. J. Borgman.—On the hysteresis and viscosity of dielectrics, by M. F. Beaulard. From the results of the experiments given, the author concludes that dielectrics do not present the phenomenon of hysteresis, but are only endowed with viscosity.—On samarium, by M. Eug. Demarçay. The properties of the samarium isolated by the method of double magnesium nitrates previously described are so well defined that it would appear to be a simple substance analogous to other elements and not a mixture. The pale yellow colour of the oxide is apparently not due to any impurity. The atomic weight, as determined by the sulphate method, is about 147·5.—On the combination of sulphur dioxide with metallic iodides, by M. E. Péchard. Potassium iodide, either in solution or in the solid state, rapidly absorbs sulphur dioxide, the compound $KI.SO_2$ being formed. This compound is easily dissociated into its constituents, its dissociation pressure at 0° being 60 cm. of mercury, at 30°, 238 cm. Other iodides form similar compounds.—On the gases emitted by the Mont Dore springs, by MM. F. Parmentier and A. Hurion. The gas is carbon dioxide containing 0·49 per cent. of nitrogen and ·01 per cent. of argon. —Bromination with aluminium bromide, by M. Ch. Pouret. Organic chlorinated compounds, heated to their boiling points for some time with aluminium bromide, give good yields of the corresponding bromine derivatives. The preparation of bromoform, methylene bromide, methyl bromide, ethyl bromide, pentabromethane, ethylene, ethylidene and acetylene bromides is described in detail.—The action of monochloracetic esters upon the sodium derivative of acetylacetone, by M. F. March. The compounds $(CH_3.CO)_2.CH.CH_2.CO.OC_2H_5$ and $(CH_3.CO)_2.CH.CH_2.CO.OCH_3$ are described; and also the products of the reaction between these bodies and phenylhydrazine.—Action of ethylidene chloride upon phenols in presence of potash, by MM. R. Fosse and J. Ettlinger.—On the presence of tyrosine in the water of contaminated wells, by M. H. Causse. The water from contaminated wells at Lyons gave an orange coloration with the chloromercurate of sodium paradiazobenzenesulphonate which proved not to be due to cystine. Tyrosine was then extracted and identified by analysis.—On some changes which occur in plants grown in the dark, by M. G. André. A set of comparative analyses of maize and lupin plants grown in sunlight and in the dark.—Studies in development of *Petromyzon Planeri*, by M. E. Bataillon.—Modifications in structure observed in cells undergoing a true fermentation, by MM. L. Matruchot and M. Molliard. The fermentation of the fruit of *Cucurbita maxima* was carried out under conditions excluding the possibility of intervention of any foreign organisms. Every cell in a state of true fermentation shows a very clear nucleus, a small amount of chromatine arranged on the periphery of the nucleus, a protoplasm full of vacuoles, and numerous minute drops of essential oil formed in the protoplasm.—Botanical zones in French Western Africa, by M. A. Chevalier.—On the granites and syenites of Madagascar, by M. A. Lacroix.—On the Gothlandian of the Peninsula of Crozon (Finisterre), by M. F. Kerforne.—Influence of temperature on the fatigue of the motor nerves of the frog, by M. J. Carvallo. Temperature has a considerable influence upon the activity of motor nerves, the excitability increasing up to 20° C.—The functions of the crystalline tube of the Acephala, by M. Henri Coupin. The function of this tube appears to be digestive, a storehouse of diastases.—Topography of the mouth as regards sensitiveness of taste, by MM. Ed. Toulouse and N. Vaschide.

### AMSTERDAM.

**Royal Academy of Sciences**, March 31.—Prof. H. G. van de Sande Bakhuyzen in the chair.—On orthogonal comitants, by Prof. Jan de Vries.—On indigo fermentation, by Prof. Beyerinck. Indigo fermentation is the decomposition of the glucoside indican into indoxyl and glucose by the action of a cell. This is effected in two ways: first, by katabolism, *i.e.* by the direct action of the living protoplasm on the indican; secondly, by specific enzymes. All the indican splitting bacteria examined act by katabolism, and are quite inactive when dead. The indican plants and some kinds of yeast contain indigo enzymes, and so are still active when dead. The indigo enzymes of *Indigo leptostachya*, *Polygonum tinctorium*, *Phajus grandiflorus*, *Saccharomyces sphaericus*, and the emulsion of sweet almonds, which also acts feebly on indican, proved to be quite different enzymes with optima of activity at 61°, 42°, 53°, 44° and 55° C. respectively. The action of all of them is increased by acid to the amount of 0·5 c.c. normal per 100 c.c. of indican solution; more acid as well as alkali decrease their activity. In indigofera there is no katabolism, whilst in *Polygonum* there is a slight katabolism at low, in *Phajus* a very strong katabolism at high, temperatures. Hence the last two decompose indican in both ways at once, while indigofera does so by enzyme action only. In the leaves of *Phajus* indican is localised in the protoplasm both of the cells of the epidermis and of the mesophyll; the indigo enzyme occurs in the chlorophyll granules.—Prof. Hoogewerff presented on behalf of Mr. J. Hazewinkel, manager of the "experimenting station" for indigo at Klaten (Java), a paper, entitled "Indican, its splitting up, and the enzyme which brings this about." This paper contains the results of inquiries, made in 1898, which for technical reasons were not intended for publication. Beyerinck's publication makes further withholding useless. Mr. Hazewinkel observed that when all enzyme actions are excluded, an aqueous solution might be obtained from leaves of *Indigofera leptostachya*, which solution by the action of enzymes and subsequent oxidation yielded indigo. The glucoside-indican found in this solution appeared to be a fairly stable substance (also at boiling heat and when acted upon by alkalis), provided it was not exposed to the action of enzymes (indimulsin, emulsin) and of acids. Mr. Hazewinkel proved in various ways, among others by the formation of indizubine (with isatin), that the indigo-forming splitting-product of indican is indoxyl, and inquired into various circumstances influencing the detection of indoxyl in those solutions and the formation of indigo from indoxyl, and also observed that during the so-called fermentation of indigo leaves, no indican, but indoxyl is present in the fermentation fluid.—Prof. Hoogewerff also made a communication on behalf of Mr. H. ter Meulen and himself, entitled "A Contribution to the Knowledge of Indican." Basing their inquiries upon the above-mentioned inquiries by Mr. Hazewinkel and those made by Prof. Beyerinck, Prof. Hoogewerff and Mr. ter Meulen prepared pure indican from leaves of *Polygonum tinctorium*, cultivated by Prof. Beyerinck, and from indican solutions received from Mr. Hazewinkel. Indican crystallises out of an aqueous solution with 3 mol. $H_2O$, probably in rhombic crystals, melting at 51° and decomposing, when heated, to a higher temperature with the formation of violet vapours; it tastes bitter and is optically active, exerting a left-handed rotation. Over sulphuric acid *in vacuo* it loses its water of crystallisation; its melting point is then 100°–102°. It dissolves pretty readily in water, methyl alcohol, ethyl alcohol and acetone, and very slowly in benzole, carbon disulphide, ether or chloroform. It is represented by the formula $C_{14}H_{17}NO_6$, corresponding to the formula proposed by Marchlewski. The result obtained was 56·7 per cent. C, 5·8 per cent. H, 4·7 per cent. N; the molecular weight was determined cryoscopically. On decomposition with HCl and oxidation with air, indican yielded indirubinous indigotine. No difference was observed between indican out of *Indigofera* leaves and that obtained from *Polygonum* leaves. Further investigations were promised.—The following papers were also presented for publication in the *Proceedings*: On a special case of Monge's differential equation, by Prof. W. Kapteyn.—On the locus of the centres of hyperspherical curvature for the normal curves of *n*-dimensional hyperspace, by Prof. Schoute.—On the power of resistance of the red-blood corpuscles, by Mr. Hamburger.—(1) On behalf of Mr. J. D. van der Waals, junr., a paper on equations, containing functions for different values of the independent constant; (2) on behalf of Dr. J. Verschaffelt, a paper on the critical isotherm and the densities of saturated vapour and liquid in the case of isopentane and carbonic acid, by Prof. van der Waals.—On the 14-monthly period of the motion of the earth's pole, with determinations of the azimuth of the meridional signs of the Leyden Observatory in the years 1882–1896, by Prof. H. G. van de Sande Bakhuyzen, on behalf of Mr. J. Weeder.—Prof. Hoffman presented for publication in the *Transactions* a paper, entitled "Zur Entwicklungsgeschichte der Sympathicus."

---

## DIARY OF SOCIETIES.

### *THURSDAY*, May 10.

Royal Society, at 4.30.—On the Diffusion of Gold in Solid Lead at the Ordinary Temperature: Sir W. Roberts-Austen, F.R.S.—On Certain Properties of the Alloys of Gold and Copper: Sir W. Roberts-Austen, F.R.S., and Dr. T. K. Rose.—Experiments on the Value of Organic Sensation as Contributory to Emotion: Prof. Sherrington, F.R.S.—On the Brightness of the Corona of April 16, 1893. Preliminary Note: Prof. Turner, F.R.S.—The Radio-Activity of Uranium: Sir W. Crookes, F.R.S.

Royal Institution, at 3.—A Century of Chemistry in the Royal Institution: Prof. J. Dewar, F.R.S.

Mathematical Society, at 5.30.—Special Meeting.—The Differential Equation whose solution is the Ratio of Two Solutions of a Linear Differential Equation: M. W. J. Fry.—A Congruence Theorem relating to Eulerian Numbers and other Coefficients: Dr. Glaisher, F.R.S.—Linear Substitutions Commutative with a given Substitution: Dr. L. E. Dickson.

Institution of Electrical Engineers, at 8.—A Frictionless Motor Meter: S. Evershed.

Iron and Steel Institute, at 10.30.—Ingots for Gun Tubes and Propeller Shafts: F. J. R. Carrulla.—The Manufacture and Application of Water-Gas: Carl Dellwik.—The Equalisation of the Temperature of Hot Blast: Lawrence Gjers and Joseph H. Harrison.—The Manganese Ores of Brazil: H. Kilburn Scott.—The Utilisation of Blast-furnace Slag: Ritter Cecil von Schwarz (Liége).

### *FRIDAY*, May 11.

Royal Astronomical Society, at 8.—On the Alleged Rotation of the Spiral Nebula M 51 Canum Venat: H. H. Turner.—Observations of Minor Planets at Windsor, New South Wales: John Tebbutt.—The Duration of the Greater Sun-spot Disturbances for the Years 1881 to 1899: Rev. A. L. Cortie.—Note on Measures by Prof. Barnard of Two Standard Points on the Moon's Surface: S. A. Saunder.—Micrometrical Measures of Double Stars: W. Coleman.—Diagrams for Planning Photographic Observations of Eros: A. R. Hinks.

Physical Society, at 5.—Discussion of Prof Lodge's Paper on the Controversy concerning Volta's Contact Force.—The Heat of Formation of Alloys: Mr. J. B. Tayler.—On the Want of Uniformity in the Action of Copper-Zinc Alloys on Nitric Acid: Dr. Gladstone, F.R S.—An Electromagnetic Experiment, and Experiments illustrating the Aberration called Coma: Prof. S. P. Thompson, F.R.S.

Malacological Society, at 8.—On a New Species of *Despoena*, Newton (*Proserpina*, Gray): with Notes on some Allied Forms: E. R. Sykes.—On some New Mollusca from the Philippines: G. B. Sowerby.—On some Lamellibranch Remains occurring in a Sandstone from the Malay Peninsula: R. Bullen Newton.

### *SATURDAY*, May 12.

Royal Institution, at 3.—South Africa: Past and Future: Dr. Alfred P. Hillier.

### *MONDAY*, May 14.

Society of Arts, at 8.—The Incandescent Gas Mantle and its Use: Prof. Vivian B. Lewes.

Royal Geographical Society, at 8.30.—Nature and Man in British New Guinea: Prof. A. Haddon, F.R.S.

### *TUESDAY*, May 15.

Royal Institution, at 3.—Brain Tissue considered as the Apparatus of Thought: Dr. Alex Hill.

Anthropological Institute, at 8.30.

Royal Statistical Society, at 5.—Municipal Finance and Municipal Enterprise: Sir H. H. Fowler.

THURSDAY, MAY 17, 1900.

## *BIOLOGY AS AN "EXACT" SCIENCE.*

*The Grammar of Science.* By Karl Pearson, M.A., F.R.S., Professor of Applied Mathematics and Mechanics, University College, London. Second Edition, revised and enlarged, with 33 figures in the text. Pp. xviii + 548. (London: Adam and Charles Black, 1900.)

THE sciences of life are marked off for practical purposes from those concerned with inorganic matter by obvious differences in the nature of the material with which they respectively deal. But in addition to distinctions of this kind, it has been customary to look upon biology as having a lower claim to the title of an "exact" science than that enjoyed, for example, by chemistry and physics. This view has been emphasised by the practice of calling biology a merely "descriptive" science, with a kind of implication that other sciences are that and something more. The distinction, however, is at best an artificial one, resting mainly on the fact that the conditions of life are often so complex, and the data so difficult of access, that the use of those quantitative methods of induction which in other sciences have been fruitful of important results, so far as biology is concerned has to a great extent remained in abeyance.

It could not be expected that this state of things should be allowed to continue. "Every science," said Stanley Jevons, "and every question in science, is first a matter of fact only, then a matter of quantity, and by degrees becomes more and more precisely quantitative." In those parts of biology which come into relation with chemistry and physics, the quantitative methods have long since gained a footing. Physiology tends increasingly to become a science of exact measurement, and there is abundant scope for the exercise of mathematical power in the investigation of its present data. With regard, however, to many problems of what is known as "general biology," especially those which gather round the central doctrine of evolution, it is no doubt true that until recently measurements have either not been applied at all, or have been used only in the simplest and crudest form. That general biology has now ceased to deserve the reproach of neglecting quantitative methods is largely due to the labours of Mr. Francis Galton, Prof. Weldon, and Prof. Karl Pearson; the way towards a greater precision of method having also been in some degree prepared by other workers, such as Milne Edwards, J. A. Allen and A. R. Wallace.

In the second edition of his well-known "Grammar of Science," Prof. Pearson has included two new chapters which contain a semi-popular account of his recent work on the mathematical aspects of evolutionary theory. The ground covered is extensive, comprising quantitative investigations of variation, correlation, selection in its various forms, heredity and reversion. Those readers who may be deterred by the length and elaboration of Prof. Pearson's papers in the *Proceedings* and *Philosophical Transactions* of the Royal Society will here find a clear account of the various problems concerned, together with a tolerably easy explanation of the mathematical processes involved in their attempted solution, and a useful summary of the results so far arrived at. The author states his main position as follows:—

> "What we need in the theory of evolution is quantitative measurement following upon precise definition of our fundamental conceptions. Biologists, even as physicists have done, must throw aside merely verbal descriptions, and seek in future quantitative precision for their ideas."

In the same spirit, Prof. Weldon remarked in his Presidential Address to Section D at the Bristol meeting of the British Association: "Numerical knowledge of this kind is the only ultimate test of the theory of natural selection, or of any other theory of any natural process whatever." That these dicta are substantially true will hardly be questioned, though it may be objected to Prof. Pearson that he somewhat overstates his case. All concrete science is in its essence descriptive, and it is not improbable that parts at least of biological study will have to remain indefinitely in the condition of "merely verbal description." It would appear, too, that in his eagerness to denounce the putting forward of inadequate hypotheses, the author allows himself to undervalue those rough preliminary generalisations which have frequently formed so useful a step in the completion of a great induction. It is possible to attach too much importance to Faraday's famous saying. If every "suggestive thought" which has eventually turned out to be imperfect, or even erroneous, had been "crushed in silence" instead of being given to the world, the cause of scientific progress would have suffered. We must often, for practical purposes, be content to proceed by the method of successive approximation. The work of Darwin himself was only to a limited extent quantitative.

Evolutionists of what may perhaps without offence be called the "orthodox" type, will find Prof. Pearson's attitude towards most controverted points sufficiently correct. Thus, without denying the possibility of a bathmic element in evolution, he does not countenance the "inherent growth-forces" that find favour with Neo-Lamarckians. Demonstration of the inheritance of acquired characters he holds to be still wanting; tradition, on the other hand, is probably an important factor in what are called the "instincts" of the lower animals. He finds no quantitative evidence for telegony, the occurrence of which alleged phenomenon "seems both mechanically and physiologically inconceivable." The reality of natural selection as a factor in evolution is quantitatively demonstrable, and sexual selection is rehabilitated.

It would be impossible within the limits of a notice like the present to do justice to the lucidity of Prof. Pearson's explanations, the ingenuity of his mathematical devices, and the care with which he has avoided possible sources of error in his calculations. Examples may be found in his exposition of the technical terms "modal value" and "standard deviation"; in his determination of the coefficient of regression; and in his discussion of the relative value of selective and non-selective death-rates for organs of different sizes. Among the most valuable of his suggestions are those on the importance of correlation; on selective mating in its various forms (including autogamy, endogamy, homogamy, preferential mating or "sexual selection" in Darwin's sense, and heterogamy); and on "genetic selection" or the inheritance of fertility. The last-named principle promises to be of special weight as a factor in evolution, though the proof of definite correlation of other physical characters with that of fertility must still be considered incomplete. The analysis of natural selection into autogeneric, heterogeneric and inorganic selection ("intra-selection" being ignored) is useful, and might have been carried still further.

A contribution to the theory of evolution so original and stimulating as Prof. Pearson's must necessarily run the gauntlet of much adverse criticism. This will probably take the form rather of objection to certain points of detail than to the general drift of his method. Certainly some passages and expressions seem capable of amendment. It is, for instance, scarcely allowable to speak of the approach of the coefficient of correlation to unity as "the transition of correlation into causation." As the author himself elsewhere points out, correlation does not imply causation, though the converse is no doubt true enough. The principle of recognition-marks in their widest sense seems again to deserve more consideration than it receives at his hands. They are requisite to ensure the actual effectiveness of the impulse towards preferential mating. It is worth notice in this connection that the author's view as to the species-forming tendency of differential fertility (which is distinct from "physiological selection," as understood by Romanes) is well exemplified by Dr. Jordan's work on "mechanical selection." In speaking of hybridisation with reference to atavism, the "Grammar" does less than justice to observed facts. The evidence afforded by crosses, such as those so carefully investigated by Standfuss at Zürich and by Prof. Cossar Ewart at Penicuik, has a bearing on heredity and atavism which cannot safely be ignored. Prof. Pearson contents himself with saying that in such cases, "from physiological and mechanical reasons, the gametes produce a zygote which does not give an individual blending the ancestry. Here any singularity almost may be expected." This statement, to say the least, seems wanting in precision. Again, a severe critic might allege that the author is apt to assume theoretical values (as in the case of the resemblance of first cousins) which have not stood the test of rigid proof.

We have not yet learned to like the new term "apolegamy," nor such a phrase as "a comparative few zygotes" (p. 453). The remarkable form of a sentence on p. 461 is probably due to a printer's error, as also the substitution of DAG for FAG at the bottom of p. 447. These, however, are small matters, and do not detract from the value of the book.

We must not be led into a discussion of the earlier chapters, a notice of which appeared in these columns at the time of their original publication. There is, however, one point on which we cannot refrain from joining issue. Prof. Pearson takes biologists to task for the loose way in which they often use such terms as "matter," "force" and "motion," as if no important questions lay behind them. Now it is certain that, in their employment of these expressions, biologists have no desire whatever to prejudice any philosophical problems. When metaphysicians and physicists are agreed about the definition of these terms, the biologist will doubtless be quite ready to follow suit. Meanwhile he must be allowed the use of ordinary language. But Prof. Pearson maintains that if these words are used in their everyday, or, as he calls it, their "figurative" sense, they ought to be defined. Why so? No definition is required for the particular end in view. Supposing an opponent were to say that the "matter" of the argument was not "attractive," and that there was no "force" in this or that contention, would the Professor waste time in making him define his terms? Can we not "beat about the bush" without entering into explanations that would satisfy the schoolmaster and the botanist? It would seem that here the Professor once more overshoots his mark.

It will be convenient to give, in conclusion, a summary of the main contention of these new chapters in the author's own words, as follows:—

"It is not absence of explanations, but rather of the quantitative testing of explanations, which hinders the development of the Darwinian theory." "The problem of the near future is not whether Darwinism is a reality, but what is quantitatively the rate at which it is working and has worked."

It is noteworthy to find him adding:—

"If that problem should be answered in a way that is not in accordance with the age of the earth, as fixed by certain physicists, it by no means follows that it is biology which will have to retrace its steps. When the rate is determined, it will be as exact in its nature as physical appreciations; and it will be a question of superior logic, and not of the superiority of the 'exact' over the 'descriptive' sciences which will have to settle any disagreement of biology and physics." . . . "It is a question of the *rate* of effective change, and when the biologists are in a position to make a definite draft on the bank of time, their credit will be just as substantial as that of the so-called exact sciences."

These last sentences, as coming from a mathematician, are highly significant; and we cannot but admire the courage that has given them expression. F. A. D.

## HERTZ'S MECHANICS.

*The Principles of Mechanics presented in a New Form.* By Heinrich Hertz. Authorised English Translation, by D. E. Jones and J. T. Walley. Pp. xxviii + 276. (London: Macmillan and Co., Ltd., 1899.)

GREAT expectations were aroused by the publication, in 1894, of a book by Heinrich Hertz, with the title, "Die Principien der Mechanik in neuem Zusammenhange dargestellt." Perhaps it would set out the received theory of dynamics in strictly logical sequence; perhaps it would present a complete theory of energy independent of the notion of force; perhaps it would bridge the gap between the molecular and mechanical standpoints. Whether it would do any of these things or not, what Hertz might have to say would certainly be worthy of attention. Hertz died before the work was printed, and the task of seeing it through the Press was entrusted to Dr. P. Lenard. He tells us that the author had devoted the last three years of his life to the book, the last two being spent in perfecting its form; and, although there are indications that he was not even then completely satisfied, the work may fairly be regarded as the mature expression of his deliberate thought on the subject.

The book opens with a preface by Helmholtz, followed by the author's preface; then there is an introduction, and the author's theory is formulated in two books:—Book i.: Geometry and kinematics of material systems; Book ii.: Mechanics of material systems. Helmholtz's preface contains an account, which might be called an appreciation, of the scientific work of Hertz, and is further remarkable for the statement that, while Kelvin, Maxwell and Hertz appear to have derived fuller satisfaction from explanations of physical facts founded on some simple general conception, such as Hertz's "straightest path," he, for his part, had felt safer in adhering to the representation of physical facts and laws by systems of differential equations. In his own preface the author tells us that his object was "to fill up the existing gaps, and to give a complete and definite presentation of the laws of mechanics which shall be consistent with the state of our present knowledge, being neither too restricted nor too extensive in relation to the scope of this knowledge"; and that what he hoped was new in his work was "the arrangement and collocation of the whole—the logical or philosophical aspect of the matter."

In the introduction the author criticises the received theory of dynamics and the more modern doctrine of energetics, and proceeds to explain the character of the new theory which he proposes. The novelty consists in this: whereas the other two theories started from four fundamental concepts—space, time, mass and force, or energy—he requires only three—space, time and mass—and the hypothesis of concealed masses. In Book i. relations concerning spaces and times are considered, and we have a generalisation of ordinary kinematics, including definitions of the path and velocity of a material system, and its shortest and straightest paths. By a material system is meant what in the ordinary presentation of dynamics would be called a system of particles with invariable connections. Some of the definitions referred to contain arbitrary elements, but they are, at any rate, simple. The definition of *mass* might have been omitted with advantage. In Book ii. the author enunciates his "fundamental law"—that every free system moves in a straightest path. This law may be looked upon as an interpretation of the principle of least action for systems of which all the energy is kinetic, or as an extension of Gauss's principle of least constraint. He proceeds to show how the motions of systems which are not free can be brought under the fundamental law by means of the hypothesis of concealed masses—the visible system is regarded as linked on to another system by invariable connections—and it is proved that the equations of motion of the system contain terms which correspond to the "forces" of ordinary dynamics. It is, perhaps, not remarkable that the dynamics of distant gravitating bodies, which was the immediate object of the received theory, should offer special difficulties from the present point of view (§ 469); on the other hand, it is claimed that the new minimum principle is applicable to invariable connections of the type of pure rolling, in which the velocities are connected by non-integrable equations, and that it thus includes more phenomena than the principle of least action. A considerable portion of Book ii. is taken up with the consideration of cyclical systems. Hertz has here developed important conceptions due to Helmholtz. Throughout both books the "older synthetic method," that of a chain of propositions, has been adopted in order that the logical purity of the theory might be beyond dispute.

Whatever may be the influence exerted on the progress of mechanics by Hertz's kinematical generalisations and fundamental law, there cannot be any doubt of the value of his criticisms of existing dynamical theories. He has explained, in the clearest manner, the object of physical theories, and stated the conditions which such theories must satisfy. He has tested the received theory of dynamics—that which is associated with the names of Galilei, Newton, d'Alembert and Lagrange—in respect of logical permissibility, and in respect of appropriateness as an expression of facts. Concerning this representation of physical experience, he asks: "Is it perfectly distinct? Does it contain all the characteristics which our present knowledge enables us to distinguish in natural motions?" And his answer is "a decided—No." He has put his finger on the weakest part of the theory—the relation of the notion of internal stress to that of equal and opposite distance-actions. He makes the supposition that the theory can, even here, be rendered rigorous, and prefers to base his attack on the complexity of the various actions which the theory needs to assume. In a somewhat similar spirit he discusses the representation of physical facts by means of the theory of energy, although it is rather the logical permissibility than the appropriateness of this representation that is called in question.

The translators have done their work well on the whole. Here and there they have been too literal, or not literal enough; they have left some obvious misprints in the German text, and some in the translation, uncorrected; but these are slight blemishes, and we must be grateful to them for a rendering which admirably conveys the spirit of the original. Their translation should serve to make more widely known a book which certainly ought to be read by all who wish to have clear ideas concerning the most fundamental of the physical subjects.

## *ASSYRIAN AND BABYLONIAN ASTROLOGY.*

*The Reports of the Magicians and Astrologers of Nineveh and Babylon.* By R. C. Thompson. Vol. i. Pp. xviii + 85 plates of cuneiform text. Vol. ii. Pp. xci + 148. (London: Luzac and Co., 1900.)

IT is now about thirty-five years ago since the late Edward Hincks, whose name will be honourably coupled with the history of cuneiform decipherment, astonished many folk by declaring that he had discovered in the British Museum tablets which related to the pseudo science of astrological astronomy. And it is not surprising that such a declaration evoked general interest, because reasonable grounds existed for hoping that when the texts on the tablets had been deciphered, some trustworthy information about Chaldean astronomy might be forthcoming. The labours of Hincks were followed by those of Lenormant and Oppert, but they had little result, because neither of these scholars was able to devote sufficient time to the study of original texts in the British Museum. Great impetus was given to the study when the late Sir Henry Rawlinson published the third part of the "Cuneiform Inscriptions," and Prof. Sayce found therein material for his paper on the "Astronomy and Astrology of the Babylonians," which appeared in 1873. During the last twenty-five years the astronomy of the Babylonians has been discussed by Strassmaier, Jensen and others, but little has been done for the older, sister subject of astrology. In the two volumes before us Mr. Campbell Thompson gives us the cuneiform text of what is, practically, the complete series of the Astrological Reports of the Royal Library at Nineveh—that is to say, copies of about two hundred and eighty tablets, and transliterations of about two hundred and twenty duplicates, without reckoning the transliterations of the texts of the original series. In addition, we find a translation of the tablets in English, and a vocabulary, with references, and a subject index. The work in each of these sections has been carefully done, and we welome Mr. Thompson in the little band of English Assyriologists, because his pages, somehow, suggest that he intends to try to justify his position as assistant in the British Museum. The study of Biblical parallels and the making of Biblical comparisons are interesting and useful enough in their way, but it is useless to dogmatise about any branch of Assyriology as long as the literature relating to it remains unpublished. Mr. Thompson's book is a good proof of this contention. Many have talked glibly and written vaguely about Chaldean astrologers, but now that we have before us the actual texts of the documents which they drew up, we shall find that most of what has been written on the subject before is incorrect.

The study of astrological astronomy in Western Asia is very ancient, and an old tradition, referred to by Pliny, states that the Babylonians possessed records of calculations which covered a period of 490,000 years; there is no doubt that we now possess texts of this class which are as old as the reign of Sargon of Agadhe (about B.C. 3800); but nothing older than this date has yet been unearthed. The principal astronomical schools in Assyria in the seventh century B.C. were at Ashur, Nineveh and Arbela, and at a later period Sippar, Borsippa and Orchoe, in Babylonia, were famous for their schools. The chief duty of the astrologer in Assyria was to calculate times and seasons, which he did either by observation or by the help of an instrument called *abkallu shikla*—*i.e.* "master of measure" (*or* reckoning). This instrument may be the clepsydra, which Sextus Empiricus says was known to the Chaldeans. The time measure was called *kasbu*, and contained two hours; the month was one of thirty days, and the year contained twelve months. The Assyrians employed one intercalary month (second Adar), and the Babylonians two (Elul and Adar). Both nations had a year of lunar months, and much of the time of the Chaldean star-gazer was spent in observing the sun and moon, with the view of determining when the months began and ended. The seven planets were called Sin (moon), Shamash (sun), Umunpauddu (Jupiter), Dilbat (Venus), Kaimânu (Saturn), Gudud (Mercury), and Mushtabarrû-mûtânu (Mars). From these, and the Signs of the Zodiac, and indeed most heavenly bodies, omens were deduced, and from the horns of the moon many portents were derived. Another source of omens were the halos, two of which were known; the one was of 22°, and the other of 46°. Dark halos always portended rain, and were well known, and Mr. Thompson suspects that the astrologers were acquainted with mock suns also. That they were good weather prophets is tolerably clear from many indications; indeed, it would be surprising if they were not. The omens derived from eclipses are very interesting, but the train of reasoning which guided the composition of birth portents cannot always be followed. Thus, in text No. 277, it is related that a certain butcher, called Uddanu, reported to an astrologer that when his sow littered, one of the young pigs had eight legs and two tails, and that he had preserved the animal in brine; from this birth the astrologer deduced the omen that the Crown Prince of the day would "grasp power." But why? Many of the reports sent to the king are interesting, chiefly because of the variety of their contents. When the astrologer had reported the astrological fact asked for, he added any little detail concerning mundane affairs which he might have room for on the tablet, or which he thought it would amuse the king to have knowledge of. Sometimes there is nothing of special astrological importance in the report at all—*e.g.* No. 22, whereon the writer wishes the king power and riches, and says that as the gods Ashur, Shamash, Nebo and Merodach have delivered Kush and Egypt into his hands, even so will they deliver the Cimmerians and the Mannai. Again, in No. 124, more than one-third of the report is occupied with the discussion of some private affair, in which the writer says, "Now the king knows I hold no land in Assyria." From the literal translations which Mr. Thompson gives in the second volume of his book, it is clear that the writers of these reports wilfully obscured their meaning by using obscure and difficult words, and that they intended to make it necessary for their recipients, royal or otherwise, to call in the professional astrologer. If the Assyrians found it difficult to get out a meaning from such documents, there is small wonder that we, in these days, have a difficulty in understanding them also, and as many of the allusions must necessarily be unknown to us, we may have to wait for new texts which will help us to clear them up. Meanwhile, Mr. Thompson has dealt carefully with his texts, and has erred rather on the side of being too literal than too paraphrastic in his translations. It is to be hoped that he will find time to continue his investigations, and to give us accurate editions of original documents, which may serve as the foundation of a superstructure of facts rather than theories.

---

## *THE SCIENCE OF NUMBER.*

*Éléments de la Théorie des Nombres.* Par E. Cahen. Pp. viii + 404. (Paris: Gauthier-Villars et Fils, 1900.)

TO the contemplative mind the science of arithmetic offers irresistible, if tantalising, attractions. The abstract notion of number underlies all scientific knowledge and theory whatever; and it is in terms of it alone that we are compelled to seek for the ultimate statement of the facts of the sensible world. It is most unfortunate that arithmetic should be so often confounded with the vulgar art of logistic—the necessary, but ignoble, reckonings of the exchange and the market-place. Even those who are aware of the distinction often fall into another error, which is almost equally pernicious. To most of them scientific arithmetic means the "Theory of Numbers," a term which they vaguely associate with an unknown, mysterious branch of mathematics with which only a few eccentric specialists have any concern.

The facts of the case are very different. It is true, of course, that the exact and logical foundation of the very rudiments of arithmetic has required the efforts of a series of the greatest intellects; that in order to follow its numerous ramifications, and appreciate its relation to other parts of analysis, demands a large amount of ability and perseverance; and that many of its truths have, as yet, only been proved by elaborate, one may even say artificial, methods; while other theorems, almost certainly true, still baffle all attempts at demonstration. But, in spite of all this, it may be asserted that arithmetic requires less apparatus and less preliminary training than any other branch of mathematics; and that, whether as a recreation or as a field for research, it amply rewards a very moderate degree of application.

It is not without reason, therefore, that Prof. Cahen addresses himself deliberately to amateur mathematicians; and, in fact, any one gifted with common sense, unspoiled by a vicious course of school instruction, ought to profit by his lucid and entertaining pages. In six chapters he deals in sufficient detail, and with appropriate numerical illustration (a most important point), with the elementary definitions and laws of operation, with linear and quadratic congruences, and with the elementary theory of binary quadratic forms. After this come a series of notes, ranging from scales of notation to an outline of the properties of Gauss's complex integers and their nearest allies; and, finally, a very useful set of tables, which afford the reader material for those applications to particular cases, without which the general theory cannot possibly be mastered.

The appearance of this work, as well as of others with a similar object in view (for instance, M. J. Tannery's excellent "Leçons d'Arithmétique"), encourages the hope that some improvement may be effected in the teaching of arithmetic in schools, and that a sound knowledge of its first principles may cease to be the monopoly of a very small minority of University graduates. It is, unfortunately, true that a very large proportion of class-books, both in arithmetic and in algebra, contain half-informed, misleading attempts at expounding theory which are really worse than the old-fashioned bundles of "Rules"; and unless these are replaced by something better, the efforts of reformers will have the lamentable result of producing a state of things worse than the old routine: a mere jargon of pseudo science, a barbarous patchwork of sham "Principles."

M. Cahen's work will be found of interest, not only by the amateur in search of recreation, but by intelligent teachers and arithmeticians of every degree of proficiency; while the professed devotees of the science will look with pleased anticipation for the more extended work on the same subject which the author appears to be preparing.

G. B. M.

## OUR BOOK SHELF.

*Atlas of Urinary Sediments, with special reference to their Clinical Significance.* By Dr. Hermann Riedel. Translated by F. C. Moore, M.Sc., M.D. Victoria. Edited and Annotated by Sheridan Delépine, M.B., C.M. Edinburgh, B.Sc. Pp. viii + 111, and 36 plates. (London: C. Griffin and Co., Ltd., 1899.)

THE work before us, as is evident from its title, is an atlas, and will be of interest rather on account of its plates, which are very beautiful, than of its letterpress; this latter, however, which is situated at the end of the book, covers more than a hundred pages, and is provided with a bibliography and an index of authors and subjects. The text is sub-divided into an introduction and two parts. The introduction deals with methods of collection and examination, &c. Part i. is devoted to unorganised, Part ii. to organised sediments. The editor has added considerably to the original text, his remarks being indicated by parentheses: he occasionally differs with Dr. Riedel concerning fact. The large additions to the text made by the editor have rather altered the character of the work, and have probably increased the sphere of its usefulness.

Under organised sediments bacteria are considered. A useful chapter is to be found at the end concerning the making of permanent specimens of urinary sediments.

The book should be of value to urinologists, and the plates certainly to physicians in general. The thanks of the profession are due to the translator and the editor for making the work available to English readers, and amplifying its contents.

*Dante.* By Edmund G. Gardner, M.A. "The Temple Primers." Pp. vi + 159. (Dent, 1900.)

A VERY admirable book, by the author of Dante's "Ten Heavens." Dante was a master of the science of his time, and Mr. Gardner has shown that he has not only carefully studied the "Divina Commedia" from the point of view of literature, but has taken pains to carefully annotate all the references to the then *systema mundi* on which so much of the action of the poem depends. Diagrams and explanations are given at the end of the book, which will be found most useful by the student.

*The Farmstead.* By Prof. J. P. Roberts, Director of the College of Agriculture, Cornell University. Pp. vi + 350. (New York: The Macmillan Company. London: Macmillan and Co., Ltd., 1900.)

THIS is a very readable compendium of suggestions in regard to providing a beautiful, economical, and healthy rural home. Although written for American farmers, it contains much that is of interest to all who are concerned with a country life, and few will peruse the book without gleaning some useful hints. There are special chapters on house-furnishing, decoration, and sanitation by Prof. Mary Roberts Smith, who writes pleasantly on the lighter sides of a farmer's life. A strong case is made out for the educational opportunities of the farm, which are shown to be ample enough to satisfy the most exacting advocate of Nature Study.

W. S.

*Object Lessons in Botany from Forest, Field, Wayside and Garden.* Book ii., for Standards iii., iv. and v. By Edward Snelgrove, B.A. Pp. xviii + 297. (London: Jarrold and Sons.)

THIS is a meritorious little book, and ought to well serve its purpose of inculcating habits of accurate and precise observation in the young pupils for whom it is designed. Although we notice a few slips here and there, they are not serious ones, and are quite eclipsed by the excellent character of the book as a whole. The author is convinced, as he says in the preface, of the value of elementary botany in the education of children, and we think his book justifies his contention.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Percussion Caps for Shooting in Schools.

THE extraordinary explosive power of fulminate of mercury is known to all chemists, but it is not generally known that the explosion of a percussion cap on a gun will cause a current of air sufficient to extinguish a candle at a distance of ten or fifteen feet. The distance, of course, varies with the length and bore of the gun, and with the nature and the size of the candle. The gun must be pointed at the lower part of the wick, and in order to blow out the candle the aim at this distance requires to be nearly as accurate as would be required to make a centre with a rifle at a hundred yards. In a speech to the Primrose League on May 9, Lord Salisbury mentioned the expediency of every man having the chance to learn to handle a rifle within reach of his own cottage. By beginning with percussion caps children might be taught to handle a gun at such an early age, that, in case of invasion of this country, boys of fourteen might be able to act as soldiers, as they are said to be doing amongst the Boers at the present time. The objections to training children to handle a rifle are, first of all, the danger of the child shooting either itself or some one else; and secondly, the expense. But the inclination of children to play soldiers might readily be utilised by teaching them to handle first of all a toy gun, and then to practice shooting at a candle with caps. For those who shoot best with caps, the practice with a saloon rifle might be held out as a reward. One single-barrelled old muzzle-loading gun would suffice for many children, and as 240 caps cost a shilling, the expense of providing a gun and material for practice would be very small. LAUDER BRUNTON.

### Escape of Gases from Planetary Atmospheres.

IN NATURE of March 29 (p. 515), Dr. Stoney, in referring to a paper by the writer in the January number of the *Astrophysical Journal*, raises the question as to the correctness of the use of Maxwell's distribution of velocities in computing the escape of gases from the earth's atmosphere. He maintains that this distribution does not hold at its attenuated limits. In my paper I have not taken conditions which may exist there, but boundary conditions, which are much more favourable to the escape of the molecules of a gas, and certainly compatible with the kinetic theory, if we are to accept such a theory at all.

Of the four conditions discussed in my paper, I will only refer to the third, the data for which are based on direct observation, namely, $-66°$ C. at a height of 20 kilometres (the mean of several ascensions really giving $-65°$ C. to $-70°$ C. for a height of only 16 kilometres). The pressure is calculated from the usual exponential formula, which agrees closely with observations to this height. At these temperatures and pressures there can be no question as to the validity of the kinetic theory.

Let us assume now that the atmosphere abruptly terminates at this height, and at this temperature the loss would certainly be greater (in fact, very much greater) than under the actual conditions, where the temperature and pressure are much lower. It should also be noticed that in my tables I have assumed the atmosphere to be entirely made up of one gas—for example, helium or hydrogen. Even then only $26{\cdot}73 \times 10^{-23}$ c.c. of helium would escape in $10^7$ years. Hence the assumption that helium is now escaping from our atmosphere is without foundation. In the case of a hydrogen atmosphere only $0{\cdot}54$ c.c. will escape in one year. If the total amount of air in the atmosphere be taken approximately at $10^{24}$ c.c., and if the actual density and temperature at the outer limits of the atmosphere be also considered, it will be evident how baseless the supposition is that either helium or hydrogen is escaping. It should be further noted that Maxwell's distribution of velocities from zero to infinity is the only one giving a sufficient velocity for any escape at all, Clausius' theory not being adequate.

It was the assumption that helium is escaping from the atmosphere—since it had not been detected—that first led me to verify it on the kinetic theory of Maxwell. The discovery, by Ramsay, of helium as a constituent of our atmosphere only tends to confirm the results of my calculations of the impossibility of its escape. S. R. COOK.

Physical Laboratory, University of Nebraska, April 26.

### Racket Feathers.

YOUR able reviewer of Meyer and Wiglesworth's "Birds of Celebes" (NATURE, April 26), criticising the arguments used to account for the formation of the racket tail feathers of the parrot, *Prioniturus* (as an inherited effect of mechanical attrition on objects against which the tail is liable to be brushed—boughs, walls of nesting-hole, &c.), asks the pertinent question, why so few exposed feathers, such "as the external rectrices and remiges of all birds, and specially the lengthened feathers of wedge-shaped tails (*Dicrurus*) are neither bare nor racket-shaped nor incipiently so." The insignificant length of the outer rectrices of *Dicrurus* perhaps safeguards them; when these feathers are longer, as in the closely-allied *Bhringa* and *Dissemurus*, they *are* racket-shaped. As to the remiges and rectrices of birds generally, one feather overlies and to a great extent protects the next; but still, the outer webs *are* always very much narrowed in the outermost and most exposed feathers, less narrowed in the next, and so on till in the middle of the wing and tail (where they are well protected on both sides) they are not narrowed at all. But, while normal wing and tail feathers are exposed to attrition on one web only, long feathers standing well out from the rest are liable to have the web frayed on both sides of the shaft as far as they project beyond the other feathers, and to some extent where they rest upon the other feathers through friction against the latter. It is assumed that at some period earlier in the history of the race these elongated feathers were of the usual simple shape, but they are now known to issue from the follicles displaying peculiarities which are often much the same as those obtained by scraping an ordinary feather with a knife—namely, if the shaft is stiff and not very long, a small terminal spatule is formed (as in *Prioniturus*, *Parotia*); if the shaft is long and weak, a large spatule (as in *Tanysiptera*, *Loddigesia*). A difficulty, perhaps, to the acceptance of the theory is its apparent consequence—that epidermal (in a sense, dead) structures, like feathers, possess the power of transmitting mutilations to posterity. For my own part, I think that the modification of shape of the feathers is communicated to the sensitive tissues (much in the same way as the shape of a stick placed in the hand of a blind man is comprehended by him after touching other things with it), and that a corresponding physiological adjustment is made and gradually inherited. The result is probably not an exact recapitulation of the mutilation, but it sometimes appears to be very nearly so.

L. W. WIGLESWORTH.

Castlethorpe, Stony Stratford, April 30.

MR. WIGLESWORTH in the above note hardly does more than recapitulate the (?) arguments advanced in the "Birds of Celebes." He does not offer any explanation of the crucial difficulties indicated in the review; why "mechanical attrition on objects," or by the wind, is effective only in so few cases throughout the class *Aves* when so many species are subject to the necessary conditions; why, for instance, the species of *Palaeornis* (belonging to the same sub-family as *Prioniturus*), or those of the genus *Irissor*, do not conform to the "law"; and why one sex of a species may have "sabre wings," or spatulate ornaments in various situations, and the other sex not.

The question may also be asked *apropos* of Mr. Wigleworth's statement above, why in *Paradisea rubra* the *long* and *weak*-shafted tail feathers have the *small* spatule (which eventually vanishes) instead of a *large* one, if the knife-scraping analogy holds good?

The reasons for the *exceptions* to the author's rule is what chiefly demands an explanation, in the opinion of

THE REVIEWER.

## THE APPROACHING TOTAL ECLIPSE OF THE SUN.

THE approaching total solar eclipse, on the 28th of the present month, promises to contribute some valuable additions to our scientific knowledge of the centre of our system, inasmuch that the track of the moon's shadow on the earth's surface passes, to an unusual extent, through regions which are easily accessible. Entering the North American continent near New Orleans, in Louisiana, the central line of eclipse traverses the States of Mississippi, Alabama, Georgia and Carolina, passing on to the Atlantic from the shore of Virginia, near Norfolk. The track is thus crossed by many of the numerous railway systems of the Southern States, exceptional facilities being thereby offered to observers with large instruments. Information supplied by the U.S. Weather Bureau indicates that stations in Alabama and Georgia are most likely to be favoured with an unclouded sky; hence the expeditions from the chief American observatories will go there. Congress has voted 5000 dollars to the Naval Observatory, and 4000 dollars to the Smithsonian Institution, for the necessary equipment. The Naval Observatory staff will organise two expeditions, one going to North Carolina, the other to Georgia, so that the stations will be some 200 miles apart, and will furnish valuable evidence as to the changes to which the solar surroundings are subject.

The Smithsonian Institution will be represented by Prof. S. P. Langley, and the Princeton Observatory by Prof. Young, who will make a redetermination of the wave-length of the green corona line. Prof. Stone will conduct a party from the University of Pennsylvania, and although details are as yet unknown here, it is expected that expeditions from the Yerkes (Profs. Hale, Barnard and Frost) and Lick (Prof. Campbell) Observatories will endeavour to obtain complete spectroscopic records of the various stages of the eclipse. The latter will again use the 40-foot coronograph, giving a 4-inch disc on plates 14 × 17 inches. Prof. Pickering, of the Harvard College Observatory, proposes to make a systematic search for an intra-Mercurial planet, and will probably occupy a station in Alabama.

By the kindness of Prof. Young, the Rev. J. M. Bacon has been enabled to organise an expedition to the States, and his observations will be made in the neighbourhood of Wadesborough, near the boundary between North and South Carolina. The party will consist of the Rev. J. M. Bacon, Miss Bacon, and Mr. and Mrs. Maskelyne. The two latter observers will expose a telescopic kinematograph on the corona during totality, and also an ordinary kinematograph on the landscape during and after totality, in the hope of recording the sweep of the moon's shadow. The Rev. J. M. Bacon, using a telescopic camera, will photograph the corona at definite times with respect to mid-totality, for determining the positions of sun and moon, and will expose a long film, continuously driven, to the zenith before, during and after totality, for recording the relative brightness of the sky during and without eclipse. By means of a kite, he will also compare the temperature of the air at an altitude of several hundred feet and at ground-level. Miss Bacon will attempt to photograph the outer corona and extensions, and also a series of landscape photographs showing the gradual diminution of illumination. Special attention will also be devoted to the "shadow bands," and to making standard photographic comparisons of the light of the corona with that of the full moon.

Prof. Burckhalter, of the Charbo Observatory, will photograph the corona by means of a camera provided with revolving screens, so adjusted as to give varying exposures for the different regions.

As the eclipse will occur at the American stations at times from 1h. 30m. to 1h. 50m., we in England will be able to hear of the results obtained there before the observers in Spain have commenced operations.

After leaving the American coast, the moon's shadow crosses the Atlantic in a westerly direction, and reaches the coast of Portugal, near Ovar, about 4.0 p.m. Thence it rapidly passes across the peninsula, leaving the mainland some little distance south of Alicante, and crossing the Mediterranean to Algiers. Most of the European expeditions will have stations along this line, chiefly at Ovar, Santa Pola and Algiers. Taking the stations in the order suggested by the progress of the eclipse, the distribution of the various parties and their plan of operations will be as follows:—

*Ovar.*—At this place, some twenty miles south of Oporto, and five miles from the coast, will be stationed one of the three official expeditions sent out by the British Government, the observers being the Astronomer Royal and Mr. Dyson, his chief assistant. The former has arranged to take large scale photographs of the corona with the 9-inch object-glass of the Thomson photoheliograph at Greenwich, the primary image being enlarged by a *concave* secondary magnifier to a scale of about 4 inches to the sun's diameter, on plates 15 × 15 inches; and also photographs with the double camera used in previous eclipses, having a 4-inch rapid rectilinear lens of 33 inches focus, and another of 13 inches focus, for recording the extensions of the coronal streamers.

Mr. Dyson's programme is purely spectroscopic. He will have two slit spectroscopes belonging to Captain Hills, and will endeavour to obtain photographs of the spectrum of the "flash" and of the corona.

Prof. Müller, of Potsdam, will from this station determine the albedo of Mercury from direct photometric comparisons with Venus, which will then be near its greatest brilliancy.

*Santa Pola.*—The second British official expedition will be stationed here, some distance south of the town of Alicante, on the east coast of Spain. The party will be under the direction of Sir Norman Lockyer, who will be primarily assisted by Mr. A. Fowler, Dr. W. J. S. Lockyer and Mr. H. Payn. On their arrival at Gibraltar, they will be taken on board H.M.S. *Theseus*, of the Mediterranean squadron, which will then convey them to their destination. As at Viziadrug in 1898, and Norway in 1896, volunteers will be selected from the ship's company, and parties detailed out for every character of observation it is possible to make during a total solar eclipse; and in the interval between their landing and the final day, besides the erecting and adjusting of the instruments, the principal observers will have their time fully occupied in giving lectures, practical demonstrations, and rehearsals to the host of volunteers who will undoubtedly offer themselves.

Sir Norman Lockyer will make visual observations with a 4-inch Cooke photo-visual telescope equatorially mounted, and will give the signals for the whole of the remaining human and mechanical machinery to be set in motion. The following are the chief sections of the observers:—

*20-foot Prismatic Camera.*—This will be manipulated by Mr. Fowler, and consists of a Cooke photo-visual triplet lens, of 6 inches aperture and 20 feet 3 inches focal length. Outside this will be placed the objective prism, of 9 inches aperture and 45° angle, which was used at Viziadrug in 1898. The instrument will be fixed horizontally, and fed with light from a 12-inch siderostat. It is proposed to obtain instantaneous photographs of the chromospheric spectrum at both internal contacts, and long-exposure photographs of corona spectrum during totality. It is hoped that the greatly increased dispersion given by this instrument will increase the contrast between the *line* and *continuous* spectra of the corona, and so render more accurate measurements of wave-length possible. The plates used will be 15 × 2½ inches.

*6-inch Prismatic Camera.*—This is the same instrument which was used with success by Mr. Fowler in 1898, and will be under the charge of Dr. Lockyer. It consists of a 6-inch object-glass by Henry, of 7 ft. 6 in. focus, outside which are adjusted two objective prisms, each of 6 inches aperture and 45° angle. The programme with this instrument is similar to that of the 20-foot.

*Coronographs.*—Several coronographs of varying power are being taken, the largest being under the charge of Mr. Howard Payn, a gentleman who has generously volunteered his services for the expedition. This instrument has a Cooke photo-visual lens of 4 inches aperture and 16 feet focal length, the primary image being used on plates 12 × 12 inches.

In addition, the De la Rue coronograph (4⅝ inches aperture and 72 inches focal length), Graham coronograph (3 inches aperture, 21 inches focal length), and Dallmeyer coronograph (6-inch aperture rapid rectilinear, 48 inches focal length) will be used. Parties of the volunteers will be engaged in one or other of the following observations :—

| | | | |
|---|---|---|---|
| Disc drawings of corona ... | about | 19 | volunteers. |
| Observations of ring spectra ... | ,, | 5 | ,, |
| Observations with pocket slit spectroscopes... ... ... | ,, | 4 | ,, |
| Observations of shadow bands... | ,, | 6 | ,, |
| Observations of stars and other celestial objects visible during totality ... ... | ,, | 20 | ,, |
| Shadow phenomena, both atmospheric and terrestrial ... | ,, | 6 | ,, |
| Colours of landscape, &c. ... | ,, | 12 | ,, |
| Meteorology, temperature, pressure, &c. ... ... ... | ,, | 15 | ,, |
| Photographs of landscape ... | ,, | 5 | ,, |
| Natural history effects on men and animals ... ... ... | ,, | 3 | ,, |

In addition to these instruments, several of the observers will obtain photographs of the eclipse spectra by means of diffraction gratings and prisms fixed in front of their own small cameras. Those with gratings are likely to be specially useful, as the dispersion is sufficiently great to render it possible for the bright line spectra to show up from the continuous spectrum, and there is the further advantage of the large field given by an ordinary rectilinear, so that the spectrum of the streamers may also be obtained.

Prof. Copeland, Astronomer Royal of Scotland, will also occupy a station at Santa Pola, using a telescope of 40 feet focus.

The British Astronomical Association and the French Astronomical Society will each send parties to both Alicante and Algiers. As, however, the former place is so well occupied by Sir Norman Lockyer's party, the third official party from the British Government will occupy a station at Algiers, and will consist of Prof. Turner, Mr. Newall, Mr. Evershed and Mr. Wesley.

Prof. Turner will photograph the corona with one of the double cameras used in previous eclipses, one of which is arranged to polarise the coronal light before it reaches the photographic plate, and thereby determine the extent to which this light is initially polarised. In addition, he also hopes to repeat his work of 1893 and 1898 for determining photometrically the relative brightness of the corona at varying distances from the limb.

Mr. Newall will have three instruments under his charge, viz. :—(1) A four-prism slit spectrograph for obtaining the spectrum of the "flash," and of the corona. In the latter he hopes to obtain material for showing the difference, if any, between the spectrum of the coronal rays and the other portions. (2) An objective grating camera for photographing the spectrum of the corona in monochromatic light. (3) A polariscopic camera for photographing the corona, special attention being devoted to the study of any differences between the darker and brighter rifts.

Mr. Wesley, the assistant secretary of the Royal Astronomical Society, has for many years critically studied the minute structure of the corona, he being the draughtsman who has engraved the reproductions of many of the corona photographs of past eclipses for publication, but has not hitherto had an opportunity of studying it from nature. By the kindness of M. Trépied, the Director of the French Government Observatory at Algiers, Mr. Wesley will be enabled to examine the corona with the powerful "equatorial coudé" (about 8 inches aperture).

Mr. Evershed will not be stationed at Algiers itself, but intends to observe from a place near the limiting line of totality, about twenty miles south of Algiers, so that he may photograph the "flash" spectrum with somewhat longer exposure than near the central line.

Mr. and Mrs. Maunder will repeat at Algiers their programme so successfully carried out at Buxar, India, in 1898, but with larger apparatus. This will include short exposure photographs of the inner corona, and others with long exposure for extensions and streamers.

Mr. and Mrs. Crommelin will go to Algiers, and take photographs of the corona and of the shadow as projected on the atmosphere.

It is also stated that Mr. Percival Lowell, of Arizona, and Prof. Todd, of Amherst College Observatory, U.S.A., will occupy stations near Tripoli, in North Africa. It is to be hoped that favourable weather will enable the latter astronomer to successfully use his electrical control, by means of which he has arranged that a great number of photographic cameras shall be automatically exposed for varying times, all of which are operated from one revolving drum with delicately fitted electrical contacts.

The eclipse occurs at the European stations about 4.0 p.m. Greenwich time, so that it may be possible to communicate the results of the various expeditions to the evening papers of the same day.

Mention should be made of the generous arrangements which have been made by the authorities of all the Governments concerned, whereby the usual customs tariff and examination will be dispensed with, provided the observer is furnished with a certificate showing that his baggage is really for eclipse observation. The railway companies in Spain have also consented to convey passengers at half the usual fares.

CHARLES P. BUTLER.

## *THE ROYAL SOCIETY SELECTED CANDIDATES.*

FIFTEEN candidates were selected by the Council of the Royal Society on Thursday last for election into the Society. The following are the names and qualifications of the new Fellows :—

### GEORGE JAMES BURCH,

M.A. (Oxon). Lecturer at the University Extension College, Reading. Author of the following papers :—(1) "Experiments on Flame" (NATURE, 1885–86); (2) "A Perspective Microscope" (*Proc. Roy. Soc.*, vol. xiii.); (3) "Researches on the Capillary Electrometer" (*Proc. Roy. Soc.*, vol. xlviii., *ibid.*, vol. lix., *Phil. Trans.*, vol. clxxxiii(A)., *The Electrician*, July, 1896). "On a Method of drawing Hyperbolas" (*Phil. Mag.*, Jan., 1896). Also joint author of the following papers :—(1) "Dissociation of Amine Vapours" (with Mr. J. E. Marsh) (*Journ. Chem. Soc.*, 1889); (2) "E.M.F. of certain cells containing Nitric Acid" (with Mr. V. H. Veley) (*Phil. Trans.*, vol. clxxxii(A).; (3) "Effect of Injury in Muscle" (with Prof. Burdon-Sanderson) (*Proc. Physiol. Soc.*, 1893); (4) "Action of Concentrated Acids on Metals in contact" (with Mr. S. W. Dodgson) (*Proc. Chem. Soc.*, 1894); (5) "D'Arsonval Physical Theory" (with Mr. L. E. Hill) (*Journ. Physiol.*, 1894); (6) "The Electromotive Properties of *Malapterurus electricus*" (with Prof. Gotch) (*Phil. Trans.*, 1896).

#### *Supplementary Certificate.*

Author of the following scientific papers in addition to those stated in the first certificate :—"On Prof. Hermann's Theory of the Capillary Electrometer" (*Proc. Roy. Soc.*, vol. lx., p. 328); "The Tangent Lens-gauge" (*Phil. Mag.*, 1897, p. 256); "An Inductor-Alternator for Physiological Experiments" (*Journ. of Physiology*, vol. xxi., 1897; "An Account of Certain Phenomena of Colour Vision with Intermittent Light" (*ibid.*); "Artificial Colour Blindness, with an Examination of the Colour-Sensations of 109 Persons" (*Phil. Trans.*, vol. clxli., 1899); joint author with Prof. Gotch, F.R.S., of the following scientific papers :—"The Electrical Response of

Nerve to a Single Stimulus as investigated by the Capillary Electrometer" (*Proc. Roy. Soc.*, vol. lxiii., 1898, p. 300); "The Electrical Response of Nerve to Two Stimuli" (*Journ. of Physiol.*, vol. xxvi., 1899); "The Electromotive Force of the Organ Shock, &c., in *Malapterurus electricus*" (*Proc. Roy. Soc.*, vol. lxv., p. 434, 1900).

### T. W. EDGEWORTH DAVID,

B.A. (Oxon.), F.G.S. Professor of Geology in the University of Sydney, N.S.W. Formerly Senior Geologist to the Geological Survey of New South Wales, and author of many reports and maps issued by the Survey. Has published many papers dealing with Glacial action in recent, as well as ancient, geological periods; among others:—"Evidences of Glacial Action in S. Brecknock and E. Glamorgan" (*Quart. Journ. Geol. Soc.*, vol. xxxix., pp. 39-58, 1882); "On Evidences of Glacial Action in the Carboniferous and Hawkesbury Series, N.S.W." (*ibid.*, vol. xliii., pp. 190-197, 1887); "On Glacial Action in Australia in Permo-Carboniferous Times" (*ibid.*, vol. lii., pp. 289-302, 1896); also many papers and addresses dealing with Petrology, Vulcanology, and Stratigraphical Geology in the Southern Hemisphere, published in the *Journals* of the Royal, Linnean, and the Societies of New South Wales. Has superintenned and conducted to a successful issue the work of boring the Coral Atoll of Funafuti, undertaken by the Royal Society and the Geographical Society of New South Wales, with the assistance of the Admiralty.

### JOHN BRETLAND FARMER,

M.A. (Oxon.), F.L.S. Professor of Botany, Royal College of Science, London. Formerly Fellow of Magdalen College, Oxford. Distinguished for his Botanical and Biological researches. Author of the following papers:—"On the Development of the Endocarp in *Samlucus nigra*" (*Ann. of Bot.*, vol. ii.); Contribution to the "Morphology and Physiology of Pulpy Fruits" (*ibid.*, vol. iii.); "The Stomata in the Fruit of *Iris Pseudacorus*" (*ibid.*, vol. iv.); "On *Isoetes lacustris*" (*ibid.*, vol. v.); "On Abnormal Flowers in *Oncidium splendidum*" (*ibid.*, vol. vi.); "On the Occurrence of two Prothallia in an Ovule of *Pinus silvestris*" (*ibid.*); "On the Embryogeny of *Angiopteris evecta*" (*ibid.*); "On Nuclear Division in the Pollen-mother-cells of *Lilium martagon*" (*ibid.*, vii.); "On the Relations of the Nucleus to Spore-formation in certain Liverworts" (*Proc. Roy. Soc.*, vol. liv.); "Studies in Hepaticæ" (*Ann. of Bot.*, vol. viii.); "On Spore-formation and Nuclear Division in the Hepaticæ" (*ibid.*, vol. ix.); "Further Investigations on Spore-formation in *Fegatella conica*" (*ibid.*); "Respiration and Assimilation in Cells containing Chlorophyll" (*ibid.*, vol. x.); "Ueber Kerntheilung in Lilium" ("Flora," 1895); "On the Structure of a Hybrid Fern" (*Ann. of Bot.*, vol. xi.). Joint Author of:—with J. Reeves, "On the Occurrence of Centrospheres in *Pellia epiphylla*" (*ibid.*, vol. viii.); with J. H. Williams, "On Fertilisation and the Segmentation of the Spore of Fucus" (*Proc. Roy. Soc.*, vol. lx.); with T. Waller, "Observations on the Action of Anæsthetics on Vegetable and Animal Protoplasm" (*ibid.*, vol. lxiii.); with J. Brentland, "Contributions to our Knowledge of the Fucaceæ, their Life-History and Cytology" (*Phil. Trans.*, vol. cxc.).

### LEONARD HILL,

M.B. Lecturer on Physiology, London Hospital Medical College. Distinguished as a Physiologist. Author of the following works:—"On Poisoning by Phosphorus" (*Lancet*, 1890); "On Intra-Cranial Pressure" (*Roy. Soc. Proc.*, vol. lv.); "On Effects of Compression of the Common Carotid Artery" (with Moore) (*Brit. Med. Journ.*, 1894); "On Formation of Heat in the Salivary Glands" (with Bayliss) (*Journ. of Phys.*, vol. xvi.); "On D'Arsonval's Physical Theory of the Negative Variation" (with Birch) (*ibid.*); "On a Simple Form of Gas Pump" (*ibid.*, xvii.); "Exchange of Blood-Gases" (with Nabarro) (*ibid.*); "On Exchange of Blood-Gases in Brain and Muscle" (*ibid.*, xviii.); "On the Influence of Gravity on the Circulation" (*ibid.*); "On Intra-Cranial Pressure and the Circulation" (with Bayliss) (*ibid.*); "The Physiology and Pathology of the Cerebral Circulation," Hunterian Lectures, Churchill, 1896; "On Nervous Pressure and the Pulse" (with Barnard and Sequeira) (*Journ. Physiol.*, xxi.); "Influence of Gravity on the Circulation" (with Barnard) (*ibid.*); "The Causation of Chloroform Syncope" (*Brit. Med. Journ.*, 1897); "A Simple Form of Sphygmometer" (*ibid.*); "On Arterial Pressure in Man" (*Journ. Phys.*, xxii.); "On Rest, Sleep and Work on Arterial Pressure" (*Lancet*, 1898); "On Syncope and the Influence of Posture on Rabbits" (*Journ. Phys.*, xxii.); "On the Effects of Cerebral Anæmia produced by Ligation of the Cerebral Arteries" (with Mott) (*ibid.*, 1898); "On Human Cerebro-Spinal Fluid" (*Proc. Roy. Soc.*, 1898). In the press:—"Mechanism of the Circulation" (Schäfer, "Text-Book of Phys."); "Cerebral Circulation" (Allbutt's "System of Medicine").

### JOHN HORNE,

F.G.S., F.R.S.E. One of the Senior Geologists on the Staff of the Geological Survey of Scotland. Has been engaged for more than thirty years in the Geological Survey. From 1868 to 1876 he personally studied and mapped large areas of the Silurian uplands of Scotland. From 1876 to 1883 he surveyed extensive tracts in the counties of Nairn, Inverness, Banff and Aberdeen. From 1884 till the present time he has taken an important share in the investigation and mapping of the complicated geology of the North-West Highlands. In addition to these official researches he has devoted his intervals of holiday to original exploration, and has made important contributions to our knowledge of the glacial and volcanic geology of the Orkney and Shetland Isles. Among his papers are the following:—"A Sketch of the Geology of the Isle of Man," and the "Post-Pliocene Formation of the Isle of Man" (*Edin. Geol. Soc. Trans.*, ii., 1174, pp. 323, 329); "The Geology of the Island of Unst" (*Edin. Phys. Soc. Proc.*, iv., 1878, p. 274); "The Volcanic History of the Old Red Sandstone Period North of the Grampians" (*Glas. Geol. Soc. Trans.*, vii., 1881, p. 77). Most of his investigations have been worked out in conjunction with Mr. B. N. Peach, F.R.S., but the results have been arranged and described by Mr. Horne. Some of this conjoint work has been of the highest value, both in regard to British geology and to the theoretical treatment of the science. Special reference may be made to the "Report on the Recent Work of the Geological Survey in the North-West Highlands of Scotland" (*Quart. Journ. Geol. Soc.*, xliv., 1888, p. 378), in which the detailed structure of one of the most intricate geological regions in Europe was worked out and illustrated; to a paper on "The Olenellus-Zone in the North-West Highlands" (*ibid.*, xlviii., 1892, p. 227), which demonstrated the existence and stratigraphical relations of Lower Cambrian Rocks in Scotland; and to the large volume recently published by the Geographical Survey, on "The Silurian Rocks of Scotland" (p. 749), which gives the detailed results of a prolonged and laborious investigation by Messrs. Peach and Horne of the whole Silurian region of southern Scotland. In 1888 was awarded the Wollaston Fund by the Geological Society, and in 1899 received from the same Society, in association with his friend and colleague, Mr. Peach, a duplicate Murchison medal. Received, in 1893, the Neill medal from the Royal Society of Edinburgh, in recognition of the value of his contributions to Geology.

### JOSEPH JACKSON LISTER,

M.A., F.Z.S. Demonstrator of Comparative Anatomy in the University of Cambridge. Distinguished as a Zoologist. Was Naturalist on board H.M.S. *Egeria* in two cruises, one to Christmas Island (Indian Ocean), the fauna of which he was the first to investigate, and another in the Pacific among the Tonga, Union and Phœnix Islands, during which he made himself well acquainted with the fauna of those islands, and of the Seychelles. His researches on the Foraminifera have thrown important light on the life-history and reproduction of that group. Author of the following papers:—"On the Natural History of Christmas Island in the Indian Ocean" (*Proc. Zool. Soc.*, 1888, p. 512); "On some Points in the Natural History of Fungia" (*Quart. Journ. Micros. Soc.*, vol. xxix., p. 359); "A Visit to the Newly-Emerged Falcon Island, Tonga Group, S. Pacific" (*Proc. Roy. Geograph. Soc.*, March 1890); "Notes on the Birds of the Phœnix Islands, Pacific Ocean" (*Proc. Zool. Soc.*, 1891, p. 289); "Notes on the Natives of Fakaofu (Bowditch Island), Union Group" (*Journ. Anthrop. Inst.*, 1891, p. 43); "Notes on the Geology of the Tonga Island" (*Quart. Journ. Geol. Soc.*, vol. xlvii., p. 590); "Contributions to the Life-History of the Foraminifera" (Abstract, *Proc. Roy. Soc.*, vol. lvi., p. 155. Full paper, *Phil. Trans.*, vol. clxxxvi., 1895B, p. 401); "A Possible Explanation of the Quinqueloculine Arrangement of the Chambers in the Young of the

Microspheric Forms of Triloculina and Biloculina" (*Proc. Camb. Phil. Soc.*, vol. ix., pt. v.); with J. J. Fletcher, "On the Condition of the Median Portion of the Vaginal Apparatus in the *Macropodidae*" (*Proc. Zool. Soc.*, vol. lxiii., 1881, p. 976).

*Supplementary Certificate.*

Author of "*Astroclera Willeyana*, the representative of a New Family of recent Sponges," in the Zoological Results of Dr. Willey's Expedition, 1899.

### James Gordon MacGregor,

D.Sc. (Lond.), 1876. M.A. (Dalh.) Professor of Physics, Dalhousie College, Halifax, N.S. Well known for his long-continued Researches on Electrolytic Conductivity, on Solutions, on Resistance of Metals, and on Thermo-electricity. Author of numerous Memoirs contributed to the Royal Society of Edinburgh, the Royal Society of Canada, the Physical Society, and the British Association, including the following :—"Note on the Electrical Conductivity of Saline Solutions" (*Proc. Roy. Soc.*, Edin., 1875); "On the Electrical Conductivity of Stretched Silver Wires" (*ibid.*, 1878); "On the Variation with Temperature of the Electrical Resistance of certain Alloys" (*Trans. Roy. Soc.*, Edin., 1880); "On the Measurement of the Resistance of Electrolytes by means of Wheatstone's Bridge" (*Trans. Roy. Soc.*, Canada, 1882); "On some Experiments showing that the Electromotive Force of Polarisation is independent of the difference of Potential of the Electrodes" (*ibid.*, 1883); "On a Test of Ewing and MacGregor's Method of Measuring the Electrical Resistances of Electrolytes" (*ibid.*, 1890, with Prof. Ewing); "Note on the Volumes of Solutions" (*Brit. Assoc. Report*, 1877, with Dr. Knott); "On the Thermoelectric Properties of Charcoal and certain Alloys, with a Supplementary Thermoelectric Diagram" (*Edin. Trans.*, 1879, with Dr. Knott and Prof. Michie Smith); "The Thermoelectric Properties of Cobalt" (1876, *Proc. Roy. Soc.*, Edin., 1878); "On the Absorption of Low Radiant Heat by Gaseous Bodies" (*ibid.*, 1882–83); "On the Resistance to the Passage of the Electric Current between Amalgamated Zinc Electrodes and Solutions of Zinc Sulphate" (*Trans. Nov. Scot. Inst. Nat. Sci.*, 1883); "On the Density and the Thermal Expansion of Solutions of Sulphate of Copper" (*Trans. Roy. Soc.*, Canada, 1884); "On the Relative Bulk of certain Aqueous Solutions and their Constituent Water" (*Trans. Nov. Scot. Inst. Nat. Sci.*, 1886); "A Table of Cubicle Expansions" (*Trans. Roy. Soc.*, Canada, 1888); "On the Variation of the Density with the Concentration of Weak Aqueous Solutions of certain Salts" (*ibid.*, 1889, vol. ix., 1891); "On the Calculation of the Conductivity of Electrolytes" (*ibid.*, 1896); "On the Relation of the Physical Properties of Aqueous Solutions to their State of Ionisation" (*Phil. Mag.*, 1897); "On the Hypothesis of Abstract Dynamics and the question of the number of Elastic Constants" (*ibid.*, 1896, with Mr. E. A. Archibald); "On Calculation of Conductivities of Electrolytes" (*ibid.*, February 1898). Author of "An Elementary Treatise on Kinematics and Dynamics" (1887).

### Patrick Manson,

C.M.G., M.D. (Aberd.). F.R.C.P. (Lond.). LL.D. (Aberd.). Physician and Medical Adviser to the Colonial Office. Lecturer on Tropical Medicine, St. George's Hospital, Charing Cross Hospital and London School of Tropical Medicine. Distinguished as a Physician and Parasitologist. Discoverer of Filarial Periodicity of the *rôle* of the Mosquito in Filarial Metamorphosis; of Filarial Ecdysis; and of many other points in connection with the life-history of the Filaria nocturna. Discoverer of three other blood-worms of man, viz. *Filaria diurna*, *Filaria perstans* and *Filaria Demarquaii.* Discoverer of the disease known as Endemic hæmoptysis and of its Parasitic cause. Discoverer of *Bothriocephalus Mansoni* and of many points in connection with human and animal helminthology. Was the first to describe accurately and to name *Finea imbricata*, and to prove experimentally its dependence on a vegetable parasite. Was the first to point out the significance of the flagellated body as the initial stage of the extra-corporeal cycle of the malaria parasite, and to enunciate the hypothesis that the mosquito was the host of the parasite at this stage, and therefore an active agent in diffusing malaria, an hypothesis since proved by Major Ross to be correct. Author of a work on *Filaria sanguinis hominis* and some Parasitic Diseases of Warm Climates, 1883; of "Tropical Diseases," 1898; of the Goulstonian Lectures on the Life-History of the Malaria Parasite Outside the Human Body, 1896; of Papers on the Metamorphosis of *Filaria sanguinis hominis* in the Mosquito (*Trans. Linn. Soc.*, 1883); "On the Nature and Significance of the Flagellated Body in Malarial Blood" (*Brit. Med. Journ.*, 1894); and of many other papers on the subjects mentioned above and allied matters.

### Thomas Muir,

LL.D., M.A., F.R.S.E. Superintendent-General of Education in the Cape Colony. Distinguished as a Mathematician and Educationist. Author of "A History of Determinants," and fifty-eight original mathematical papers, including "Continuants: a New Special Class of Determinants" (*Proc. Roy. Soc. Edin.*, 1875); "On the Transformation of Gauss' Hypergeometric Series into a Continued Fraction" (*Lond. Math. Soc.*, 1876); "New General Formulæ for the Transformation of Infinite Series into Continued Fractions" (*Trans. Roy. Soc. Edin.*, 1876); "On Eisenstein's Continued Fractions" (*ibid.*, 1879); "On a Systematic Determinant connected with Lagrange's Interpolation Problem" (*Lond. Math. Soc. Proc.*, 1881–2); "On New and Recently Discovered Properties of certain Symmetric Determinants" (*Quart. Journ. Math.*, 1882); "On the Phenomena of 'Greatest Middle' in the Cycle of a Class of Periodic Continued Fractions" (*Proc. Roy. Soc. Edin.*, 1884); "The Theory of Determinants in the Historical Order of its Development" (*ibid.*, vol. xiii.–xvi.); "On Some Hitherto Unproved Theorems in Determinants" (*ibid.*, 1891); "A Problem of Sylvester's in Elimination" (*ibid.*, vol. xx.); "New Relations between Bipartite Functions and Determinants, with a Proof of Cayley's Theorem in Matrices" (*Lond. Math. Soc. Proc.*, vol. xvi.). Has rendered services of the highest importance to education in the Cape Colony, and in his capacities of trustee of the South African Museum and member of the Geological Commission has greatly promoted original scientific research in South Africa.

### Arthur Alcock Rambaut,

M.A., Sc.D. (Dublin). Radcliffe Observer. Late Royal Astronomer of Ireland. Late Andrews Professor of Astronomy in the University of Dublin. Author of the following researches in Astronomy and Physics :—Catalogue of the Mean Places of 1012 Southern Stars" ("Astronomical Observations and Researches of Dunsink," part vi.); "Catalogue of the Mean Places of 717 Stars" (part vii., *ibid.*); "On the Determination of Double Star Orbits from Spectroscopic Observations of the Velocity in the Line of Sight" (*Monthly Notices, Roy. Astron. Soc.*, vol. li., No. 5); "To Adjust the Polar Axis of an Equatorial Telescope for Photographic Purposes" (*ibid.*, liv., No. 2); "On the Inequality in the Apparent Diurnal Movement of Stars due to Refraction, and a Method of Allowing for it in Astronomical Photography" (*ibid.*, vol. lvii., No. 2); "On a Geometrical Method of Finding the most Probable Apparent Orbit of a Double Star" (*Proc. Royl. Dubl. Soc.*, vol. vii., part 2); "On the Distortion of Photographic Star Images due to Refraction" (*ibid.*, vol. viii., part 2); "On the Rotation Period of the 'Garnet' Spot on Jupiter" (*ibid.*, vol. viii., part 5); "On the Relative Positions of 223 Stars in the Cluster $\chi$ Persei, as Determined Photographically" (in conjunction with Sir R. Ball) (*Trans. Roy. Irish Acad.*, vol. xxx., part 4); "On the Possibility of Determining the Distance of a Double Star by means of the Relative Velocity of the Components in the Line of Sight" (*ibid.*, 2nd series, vol. iv., No. 6); "The Absorption of Heat in the Solar Atmosphere" (in conjunction with W. E. Wilson) (*ibid.*, 3rd series, vol. iii., No. 4).

### William James Sell,

M.A. Senior Demonstrator of Chemistry, University of Cambridge. Author of the following papers :—"Volumetric Determination of Chromium" (*Trans. Chem. Soc.*, 1879); "On a Series of Salts of a Base containing Chromium and Urea," Nos. 1 and 2 (*Proc. Roy. Soc.*, 1882 and 1889); "Anhydro-Derivatives of Citric and Aconitic Acids" (*Trans. Chem. Soc.*, 1892); "Salts of a new Platinum Sulphurea Base" (*Brit. Assoc. Rept.*, 1893); "Studies on Citrazinic Acid," Pts. I.–V. (*Trans. Chem. Soc.*, 1893–1897); "Note on the Action of Chlorine on Pyridine" (*Trans. Chem. Soc.*, 1898); "The Chlorine Derivatives of Pyridine," Pts. I.–II. (*ibid.*, 1898); "Interaction of Ammonia and Pentachlorpyridine" (*ibid.*); "Constitution of Glutazine" (*ibid.*).

### W. Baldwin Spencer,

B.A. (Oxon.), M.A. (Melbourne). Professor of Biology in the Melbourne University; formerly Fellow of Lincoln College, Oxford; Hon. Sec. of the Royal Society of Victoria; Corr. Member Zool. Soc., Lond. Distinguished as an original investigator in Zoology and Comparative Anatomy; and as a teacher and organiser. Graduated at Oxford twelve years ago. Has published more than thirty memoirs, among which are:—"On a New Family of Hydroidea Ceratellidæ" (*Trans. Roy. Soc. Vict.*, 1890); "The Anatomy of *Megascolides Australis*," and other papers on Australian Earthworms and Planarians (*ibid.*); "On New Crustacea and New Mammals," in Report of the Horn Expedition to Central Australia (which he organised); "On the Pineal Eye in Lacertilia" (*Quart. Journ. Micro. Sci.*, 1887); "On the Habits, Blood-vessels and Lungs of *Ceratodus Fosteri*"; "On a New Genus of Marsupials from Central Australia" (*Proc. Roy. Soc. Vict.*, vol. ix.); "On the Cranial Nerves of Scyllium" (*Quart. Journ. Micros. Sci.*, 1881); "On the Early Development of *Rana temporaria* (*ibid.*, 1885); "The Fauna and Zoological Relationships of Tasmania" (Presidential Address to Sect. D., Austr. Assoc. Adv. Sci., 1892).

### James Walker,

D.Sc. (Edin.), Ph.D., Leipzig. Professor of Chemistry, University College, Dundee. An active and successful worker in chemistry, especially physical and organic. Author of numerous papers, of which the following are among the most important:—"Zur Affinitätsbestimmung Organischer Basen" (*Zeit. Physikal. Chem.*, iv., p. 319, 1889); "Ueber Lösliskkeit und Schmelzwarme" (*ibid.*, v., 193, 1890); "The Dissociation Constants of Organic Acids" (*Journ. Chem. Soc.*, lxi., p. 696, 1892); "The Methyl Salts of Camphoric Acid" (*ibid.*, lxi., p. 1088, 1892); "The Electrolysis of Sodium Ethyl Camphorate (*ibid.*, lxiii., p. 495, 1893); "The Boiling Points of Homologous Compounds" (*ibid.*, part i., lxv., p. 193, 1894; part ii., lxv., p. 725, 1894); "Hydrolysis in some Aqueous Solutions" (*Proc. Roy. Soc. Edin.*, vol. xx., p. 255, 1894). Along with Prof. Crum Brown, "Electrolytic Synthesis of Dibasic Acids" (parts i. and ii. *Trans. Roy. Soc. Edin.*, vol. xxxvi., p. 211, 1891, and vol. xxxvii., p. 361, 1893). Along with J. Henderson, "Electrolysis of Potassium Allo-Camphorate" (parts i. and ii. *Journ. Chem. Soc.*, vol. lxviii., p. 337, 1895; vol. lxix., p. 748, 1896). Along with F. I. Hambly, "Transformation of Cyanate into Urea" (*Journ. Chem. Soc.*, vol. lxvii., p. 746, 1895). Along with J. R. Appleyard, "Transformation of Methylammonium Cyanates into the Corresponding Ureas" (*Journ. Chem. Soc.*, vol. lxix., p. 193, 1896).

### Philip Watts,

Naval Architect and Director of the War-Shipbuilding Department of Sir W. G. Armstrong, Whitworth and Co. Distinguished for his knowledge of the science and practice of Naval Architecture. Responsible designer of a considerable number of the swiftest and most powerful war-ships. Has done much original scientific and experimental work in connection with investigations of the stability of ships and floating bodies; the oscillations of ships in still water and amongst waves; the propulsion and manœuvring powers of ships. Was appointed by the Admiralty and acted for some years as assistant to the late Mr. W. Froude, F.R.S., on the analytical and experimental work carried on by that investigator. In that capacity he took part in the device and application of the process of "graphic integration" by which the oscillations of ships can be approximately determined under assumed conditions of wave motion, including the effect of fluid resistance. Has independently proposed a method of reducing the rolling of ships at sea, by the introduction of free water into a suitably formed chamber. This plan was adopted by the Admiralty for several important ships, after mathematical and experimental demonstration of its efficiency. Was entrusted with the experimental investigation of the turning powers of H.M.S. *Thunderer* made in connection with the work of the *Inflexible* Committee. Devised and applied methods for determining exactly the path traversed by the C.G. of the ship, the rate of acquisition of angular velocity, the angle of heel and other phenomena incidental to turning under the action of the rudder. This investigation led to subsequent modifications in the under-water form of ships, tending to increase their handiness. Is author of the following papers printed in the *Transactions* of the Institution of Naval Architects:—"On a Method of Reducing the Rolling of Ships at Sea" (1883); "The Use of Water Chambers for Reducing the Rolling of Ships at Sea" (1885); "The Italian Cruiser *Piemonte*" (1889); "The Steering Qualities of the *Yashima*" (1898); "Elswick Cruisers Built during the last Ten Years" (1899).

### Charles Thomson Rees Wilson,

M.A. (Cantab.), B.Sc. (Vict.). At present engaged in Investigations on Atmospheric Electricity on behalf of the Meteorological Council. Author of the following papers:—"On the Formation of Cloud in the absence of Dust" (*Cam. Phil. Soc. Proc.*, vol. viii., p. 306); "The effect of Röntgen's Rays on Cloudy Condensation" (*Roy. Soc. Proc.*, vol. lix., p. 338); "Condensation of Water Vapours in the Presence of Dust-free Air and other Gases" (*Phil. Trans.*, A., (1897), pp. 265–307); "On the Action of Uranium Rays on the Condensation of Water Vapour" (*Camb. Phil. Soc. Proc.*, vol. ix., pp. 333–338); "On the Production of a Cloud by the Action of Ultra-Violet Light on Moist Air" (*ibid.*, vol. ix., p. 392); "Condensation Nuclei produced in Gases by the Action of Röntgen Rays, Uranium Rays, Ultra-Violet Light and other Agents" (*Phil. Trans.*, A., 192, pp. 403–453); "Comparative Efficiency as Condensation Nuclei of positively and negatively charged Ions" (*ibid.*, A., 193, pp. 289–308).

---

## *LIEUT.-GENERAL PITT-RIVERS, F.R.S.*

BY the death of Lieut.-General Augustus Henry Lane-Fox Pitt-Rivers, F.R.S., on May 4, anthropology has lost one of her most prominent and enthusiastic students, and one whose place it will be impossible to fill.

Augustus Henry Lane-Fox was born in 1827. He served with distinction in the Crimea, at Alma and Sevastopol, being during that campaign an officer in the Grenadier Guards, and on the staff. As Lieut.-Colonel Lane-Fox he was the earliest and principal associate of Colonel, afterwards Lieut.-General, Hay, the first Commandant and Inspector-General of Musketry, and about 1855 he wrote and delivered the series of lectures which then, and since, formed a principal part of the Hythe curriculum. He had thus the honour and distinction of being prominently associated with the inauguration of one of the most important reforms in our military system. He had the unusual reputation in those days of military dandies of being an able, studious and scientific officer; but his career at Hythe was not a long one. While he was there he had the practical training and instruction of those who came to qualify as musketry instructors; and he added to, if he did not originate, the interesting collection of ancient arms and weapons and projectiles in that establishment. General Pitt-Rivers never lost his interest in military matters, and as late as 1893 he was appointed Colonel of the South Lancashire Regiment.

Few men have had the collecting instinct so strongly developed as had General Pitt-Rivers, but in his case not only were his interests extremely wide, but he had always some method in his collecting; there was invariably some principle or theory that the objects were designed to illustrate. Consequently he bought with judgment, and what in most collections are "curios" or trophies, under his arrangement became links in a chain of scientific argument, or clever suggestions of stages in the evolution of human thought or handicraft.

The spoils of over twenty years of intelligent collecting were exhibited, in 1874, in the Bethnal Green Museum, and the catalogue of this collection was published by the Science and Art Department. It is no exaggeration to say that this collection was a revelation to many people, and it and the catalogue initiated a new departure in the study of handicrafts. It was, in fact, the first practical application of the theory of evolution to objects made by man. As Colonel Lane-Fox he was, fo example, the first to demonstrate the evolutionary history of patterns, or of certain decorative features from realistic originals. He placed together, side by side, analogous objects from all parts of the world, and often he was enabled to demonstrate the origin and modifications of modern weapons, utensils, and the like. This system has its dangers; analogy may often be mistaken for homogeny, and it must be admitted that mistakes were occasionally made or wrong inferences suggested; but with care these may be greatly reduced, and this system of studying human productions appeals alike to the general public and to scientific men. We believe that the collections exhibited in 1874 were first offered to the University of Cambridge, but now they find a final resting-place in the museum at Oxford, where they have since been greatly added to and further elaborated.

Owing to the death of the sixth Baron Rivers in 1880, Mr. Lane-Fox succeeded to large estates in Wiltshire and Dorsetshire, and he assumed the name of Pitt-Rivers. This gave him his chance; many years previously his keen eye had noted the numerous earthworks and tumuli on Cranborne Chase, but he little thought that fortune would hand them over to his keeping.

In 1881 the General commenced excavating, and in 1887 he published the first of his four quarto memoirs on the results of his digging. Many burrows had been rifled before by antiquaries, but never had excavations been so systematically and thoroughly studied in this country. These memoirs are monuments to the princely liberality, technical skill, and conscientious attention to details that characterised General Pitt-Rivers.

In order to display the finds obtained in his excavations, Pitt-Rivers built a new museum at Farnham in Dorsetshire, and once more he gave rein to his passion for collecting, and soon an extensive and valuable ethnographical museum sprang up in this remote country village. Here, systematically arranged and described, may be seen models of the sites and excavations, and every specimen and fragment thence obtained. In order to illustrate the pottery which is found in various diggings, a comparative collection of pottery and ceramics was started which now forms a very valuable epitome of this industry in all ages and climes. In the same manner, a large comparative collection of agricultural implements has been collected. Here also is the collection of locks, upon which he based the memoir he published in 1883 The collections of general ethnography are surprisingly rich, and his well selected specimens of Benin metal work constitute perhaps the most representative series extant. Words fail to express one's surprise at finding this wonderful museum buried in the depth of the country.

At Tollard Royal, near Farnham, the General very carefully restored a thirteenth century house, which is known as King John's House—this he converted into a museum mainly designed to illustrate the rise of the art of painting; and with characteristic thoroughness he began with paintings of the twentieth and twenty-sixth dynasties.

Not far off are the Larmer Grounds, a park which has been beautifully laid out and provided with numerous picturesque large summer-houses for the use of excursionists. During the warm weather a band plays on Sunday afternoons, and large numbers of people avail themselves of the General's hospitality. In this effort to provide free and innocent enjoyment to the multitude, General Pitt-Rivers received much opposition from well-meaning but misguided sabbatarians; but in this as in so many other matters, he pursued what he considered to be his duty without being influenced by the opinions or opposition of others. He was very fond of joining the happy throngs, and he was never more pleased than when many thousands assembled on great occasions, such as the annual races. It is gratifying to know that his liberality was never abused by unseemly conduct.

General Pitt-Rivers' written contributions to anthropological literature were very numerous, and in his time he took an active part in the work of various societies.

General Pitt-Rivers was a Fellow of the Royal Society; on more than one occasion he was President of the Anthropological Institute; and he was a Vice-President of the Society of Antiquaries. His last public appearance was when he read an address as Vice-President of the Royal Archæological Institute at Dorchester in 1893. He was Inspector under the Ancient Monuments Protection Act of 1882, and in this capacity he visited the scheduled monuments; but even his energy was powerless to counteract the restricted powers and scope of the Act.

It would be difficult to detail the wide range of subjects that interested General Pitt-Rivers, and the remarkable knowledge he had on so many subjects. He was by no means a man whose sympathies narrowed with age. His strong physique, indomitable energy and imperious will enabled him to accomplish an immense amount of work, and his trained mind, combined with wide knowledge and sympathy, rendered that work of especial merit. Possessed of an abundance of means, he spent lavishly on his beloved science. His strenuous life was devoted to the advancement of knowledge and to the instruction and recreation of the populace.

A. C. H.

## NOTES.

The council of the Society of Arts attended at Marlborough House, on May 8, when his Royal Highness the Prince of Wales, K.G., President of the Society, presented the Albert medal of the Society to Sir William Crookes, F.R.S., "for his extensive and laborious researches in chemistry and in physics; researches which have, in many instances, developed into useful practical applications in the arts and manufactures."

The Paris correspondent of the *Times* states that the committee of the Paris Academy of Sciences has selected as candidates for election as permanent secretary, in place of the late M. Joseph Bertrand, M. Cornu, professor at the École Polytechnique, and M. Darboux Jean, of the Faculty of Sciences in Paris.

By the will of the late Mr. G. J. Symons, F.R.S., a valuable bequest is made to the Royal Meteorological Society. Mr. Symons was a great lover of old books, and had succeeded in getting together an extensive meteorological library. He bequeathed to the Society all his books, pamphlets, maps and photographs a copy of which is not already in its library. He also bequeathed his Cross of the Legion of Honour, his Albert medal, and other decorations, as well as the testimonial album presented to him by the Fellows of the Society in 1879. In addition to the above he also bequeathed the sum of 200*l*.

Mr. Goschen made an important announcement at the annual dinner of the Iron and Steel Institute last week. He said that, with a view to developing the power of English guns by means of improving the propellant agent, a committee has been appointed, with Lord Rayleigh as chairman, to investigate the whole subject. The reference to the committee is to carry out trials to ascertain what are the best smokeless propellants for use in existing guns of all natures and in existing small arms, and to report as to whether any modification in the existing designs of guns is desirable with a view to developing to the full the powers of any propellant which may be proposed.

THE King of the Belgians has created Mr. E. Windsor Richards, past president of the Iron and Steel Institute of Great Britain, a Knight Commander of the Order of Leopold.

THE Royal Commissioners who were recently appointed to inquire into and report upon the condition of the salmon fisheries of England, Wales and Scotland, commenced their inquiry on Tuesday.

FORTY-SIX of the sixty-five automobile vehicles which left London on April 23 for a 1000-mile trial, returned on Saturday last. From a report in the *Times*, we gather that the mechanical results of the trial have been very much what they were expected to be. That is to say, the established type of machine has proved itself entirely trustworthy, and between the Daimler, Napier and Panhard motors there has been, in the matter of "staying power," practically nothing to choose. Of the cars which entered, only four were driven by any other motive power than petroleum spirit, and of these one steamer only survived.

LETTERS received from Mr. Moore and Mr. Fergusson announce that the Tanganyika Expedition arrived at Lake Kivu on December 7, 1899, having left two of their party (Messrs. Berridge and Mathews) at the head of Lake Tanganyika. They had ascended the active volcano of Karunga, north of Lake Kivu (11,350 feet), but found only steam without lava issuing from the orifice. They arrived on the shores of Lake Albert-Edward on January 21, and on February 12 were at Fort Gerry, the English post in Zoru, near Mount Ruwenzori, which they were proposing to ascend.

SOME living specimens of the very curious blind fish of the caves of Kentucky, U.S.A. (*Amblyopsis spelaea*), may now be seen in the Zoological Society's fish-house, where they have been deposited by the Hon. Walter Rothschild. They are of a nearly uniform pale flesh colour. When exposed to the light these creatures hide themselves among the stones in the tank in which they are placed, though when shaded they seem to swim about pretty freely like other fishes, but usually keep near the surface.

THE Ancient Monuments Protection Bill was read a second time in the House of Lords on Tuesday. The measure extends the provisions of the Ancient Monument Act of 1882, and proposes that local authorities should be empowered to take over the charge of national monuments and to receive voluntary contributions towards the cost of maintaining and preserving them. Some of the London open spaces had been preserved in this manner, and there seemed no reason why the same principle should not be applied to monuments of archæological interest.

THE U.S. Congress has under consideration a Bill for the conversion of the present Office of Standard Weights and Measures into a National Standardising Bureau similar to the Reichsanstalt at Charlottenburg, and the National Physical Laboratory. The clause dealing with the work of the bureau reads as follows:—The functions of the bureau shall consist in the custody of the standards; the comparison of the standards used in scientific investigations, engineering, manufacturing, commerce, and educational institutions with the standards adopted or recognised by the Government; the construction when necessary of standards, their multiples and subdivisions; the testing and calibration of standard measuring apparatus; the solution of problems which arise in connection with standards; the determination of physical constants, and the properties of materials when such data are of great importance to scientific or manufacturing interests, and are not to be obtained of sufficient accuracy elsewhere.

THE gold medal of the Linnean Society of London, which is annually presented alternately to a zoologist and to a botanist, has this year been awarded to Prof. Alfred Newton, F.R.S., in recognition of his important contributions to zoological science. To the general public Prof. Newton's name will be best known in connection with the latest addition of Yarrell's "British Birds" (vols. i. and ii. of which were revised and edited by him), and the "Dictionary of Birds," an admirable compendium of ornithology. As editor of the *Ibis* (1865-70), and of the "Zoological Record" (1870-72), to which for some years previously he had supplied the annual record of the literature relating to Aves, he has placed ornithologists of all nations under great obligations to him, as he has done, also, by his publications on the avifauna of Iceland, Greenland, the West Indies, the Mascarene and Sandwich Islands, and by his articles in the "Encyclopædia Britannica" and the "Dictionary of National Biography." As chairman for many years of a committee of the British Association he has been instrumental in securing the publication of valuable reports on the migration of birds and in obtaining legislative protection for the more useful species by the appointment of a close time. The medal will be presented at the Anniversary Meeting of the Linnean Society.

THE Académie Royale de Belgique announces the following prize subjects for 1900:—*Mathematical and Physical Sciences:* A description of researches on critical phenomena in physics, together with new researches upon this subject; new researches on the viscosity of liquids; study of the derived carbonates of an element of which the compounds are still little known; the variation of latitude, together with a discussion of the reasons which have been put forward to account for it; a contribution to the algebraic and geometric study of $n$ linear forms, $n$ being greater than 3; new researches on the thermal conductivities of liquids and solutions. *Natural Sciences:* The determination of the limits of the Comblain-au-Pont formation, and the place it should occupy in geological classification. Is it Devonian or Carboniferous?; researches on the modifications produced in minerals by pressure; researches on the organisation and development of a flat-worm with the object of determining whether there exist any phylogenic relationships between Platyhelminthes and Enterocœla; does a nucleus exist in Schizophytes (Schizomycetes)? if so, what is its structure and mode of division?; researches on Devonian plants of Belgium, from the point of view of description, stratigraphical position, and, if possible, anatomical characters. The value of the gold medal to be awarded for each subject is six hundred francs. Memoirs may be written in French or in Flemish, and must be sent to the secretary of the Academy by August 1.

WE learn rom the *Electrician* that an instrument called the telephonograph, which is a modification of the phonograph, was recently inspected and tested by the German Postmaster-General and several engineers. Its inventor, Herr Paulsen, a Dane, has replaced the wax cylinder of the Edison phonograph by a steel band, and the style by a magnet energised by a telephone. Currents transmitted by the telephone pass through the electromagnet and create consequent poles on the steel band, and more or less the converse operation is employed for reproducing the sound. A long line can, of course, intervene between the transmitting telephone and the phonograph itself, and it is suggested that a telephone subscriber on leaving his office can set such a telephonograph to receive telephoned messages during his absence.

EXPERIMENTS on the exposure and development of photographic plates in ordinary light have recently been made by Prof. F. E. Nipher, and are described in *Science*. It appears that if a photographic plate in a camera is greatly over-exposed it may be developed in the light. A plate which should for ordinary work have an exposure of a second and a half for street or outdoor photography, may be exposed for two hours. When developed with weak hydrokinone by the light of a lamp, it gives a good positive. If the plate is held too near the lamp the light will dissolve a picture already appearing. If held too far away the plate begins to fog. By moving toward or from the lamp the proper illumination may be soon secured. It is remarkable that a street scene taken in this way shows not a moving thing on the streets. In Prof. Nipher's pictures, tram-cars passing every two minutes, waggons, horses, pedestrians, left no trace upon the plate. But the fixed objects are shown perfectly, with their proper shadows and high lights. Prof. Nipher points out that lantern slides and transparencies may be made directly by this method without re-photographing from a negative. Röntgen ray pictures can also be obtained upon plates which have been exposed to the light of an ordinary room for a few days, by developing in the manner described. Good radiographs have been thus produced upon plates which were uncovered during exposure to the rays.

THE usual proof that the arithmetic mean of any number of positive quantities is greater than their geometric mean consists in showing that if any two of the quantities be replaced by their semi-sum, the new series has the same arithmetic mean and a greater geometric mean. This proof, however, involves the assumption that if this process of substitution be repeated indefinitely, the ultimate result will be a series of quantities each equal to the arithmetic mean of the original series. We have never seen this property proved, and it is certainly by no means an obvious truth in the general case, for the result of the repeated operations is always a fraction whose denominator is a power of 2, while the arithmetic mean of $n$ quantities has $n$ for its denominator. We are glad to see that Mr. G. E. Crawford, writing in the *Proceedings* of the Edinburgh Mathematical Society, recommends an alternative proof in which the number of steps is finite, and the above assumption is not made. Two such proofs are possible, both of which run on somewhat parallel lines, and Mr. Crawford refers to a text-book which appeared a few years ago for the alternative to the proof now given.

WE have received from Prof. A. Klossovsky, the energetic director of the meteorological system of South-west Russia, a very valuable contribution to climatology. The work consists of two volumes, text and charts, and embraces the large area running from about the latitude of London to the northern shores of the Black Sea and the Sea of Azov, and bounded on the east by the River Dnieper. The observations used in the discussion include those made at the stations belonging both to the Central Meteorological Service of St. Petersburg and to the South-west Russian system, and embrace a period of twenty-five years (1871–1895). The tables exhibit monthly, yearly and five-yearly values of all the principal elements, and the distribution of thunderstorms and hail. The charts are coloured, and show very clearly the mean annual distribution of rainfall, the number of days of thunderstorms and hail, mean and extreme temperatures, and the distribution of cloud and humidity. The tables are arranged in various ways, and furnish most useful statistics for agriculturists and for men of science generally.

IN describing some Neocene corals of the United States (*Proc. U.S. National Museum*, vol. xxii. 1900), Dr. H. S. Gane remarks that a majority of the corals in these Eocene, Miocene and Pliocene formations belong to extinct species. They do not, however, present any close kinship with the corals of a like age in the West Indies, but are more nearly related to those now living in the Caribbean Sea and Atlantic Ocean.

MR. CECIL B. CRAMPTON, who has for some time been assistant to Prof. Boyd Dawkins in the museum at Owen's College, Manchester, has been appointed an assistant geologist on the Geological Survey of Scotland.

MR. LESTER F. WARD gives an account of the wonderful "Petrified Forest" or "Chalcedony Park" of Arizona (Report to Department of the Interior, U.S. Geol. Survey, 1900). Countless logs of silicified wood occur over a wide area in Arizona, but they are especially abundant in a particular tract known as the "Petrified Forest," east of Holbrook, between the Little Colorado and Rio Puerco. Here the logs lie in the greatest profusion, "while the ground seems to be everywhere studded with gems, consisting of broken fragments of all shapes and sizes, and exhibiting all the colours of the rainbow." These silicified blocks are not *in situ*, but have been derived from a bed of conglomeratic sandstone of Triassic age, which is exposed on the margin of a high plateau. Mr. Ward refers also to a well-known "Natural Bridge," which consists of a petrified trunk lying across a canyon, and forming a footbridge, and he observes that the trunk here is *in situ*. He advocates that means be taken to preserve these natural phenomena.

A REPORT on the proposed railway from the Commune des Houches, Bonneville, in Haute-Savoie, to the summit of Mont Blanc, has been published by M. Joseph Vallot, Director of the Mont Blanc Observatory, and M. Henri Vallot, engineer. This great undertaking was projected by M. Saturnin Fabre, but various routes have been suggested. These are fully discussed by the authors, who give reasons for recommending a route which starts from the valley of the Arve at an elevation of about 3000 feet, and proceeds by the Aiguille du Goûter and the Dôme du Goûter to a terminus at the Petits Rochers Rouges, where the elevation is about 15,000 feet. The total length of the railway would be about seven miles, and from an elevation of about 4000 feet to its upward termination, the line would for the most part be subterranean. There would be several openings, and also stations giving access to the mountain, at points of special interest and beauty. M. Joseph Vallot contributes chapters on the geology, including the glacial phenomena, and these are illustrated by a section showing the nature of the solid rocks through which the railway would be carried, and the thickness of the glacier-ice above. For a short distance the tunnelling would be made through Liassic slates and Trias with gypsum, and then wholly through various crystalline schists.

IN his memoir recently published in the *Philosophical Transactions* (see NATURE, April 19, p. 595), Mr. Oldham has shown that, in recording the movements due to distant earthquakes, the heavy vertical pendulums employed in Italy answer most readily to the early tremors, while the light horizontal pendulums of Rebeur-Paschwitz and others are most affected by the later-arriving surface-undulations. Dr. G. Agamennone has discussed the same subject independently in a note read on February 18 before the R. Accademia dei Lincei of Rome. At the Roccadi Papa Observatory, of which he is director, are two horizontal pendulums provided with mechanical registration. It is found that these instruments fail to indicate small local shocks, while in recording distant earthquakes they lag behind the vertical pendulums with stationary masses. But, by increasing the weight which the horizontal pendulums carry from 25 to 60 kg., this defect almost disappears. Dr. Agamennone therefore proposes to erect an additional pair of horizontal pendulums at Rocca di Papa in which the masses shall be at least 500 kg., the period of oscillation 10 to 15 seconds, and the magnifying ratio of the writing stiles 50, and possibly 100. He also suggests a double system of registration; the stiles at one end are to write in ink on white paper moving with a velocity of about 50 cm. per hour, and at the other end on an endless strip of smoked paper, which, on the occurrence of a shock, will be made to travel still more rapidly. The former record will enable the initial and final epochs to be determined, and the latter the period of the individual oscillations.

We have received the *Transactions* and *Report* of the Manchester Microscopical Society for 1899, which contains a good account of the late Zoological Congress, and also some well illustrated papers on various biological subjects of current interest.

Dr. C. S. Minot has favoured us with a copy of a paper from vol. xxix. of the *Proc. Boston Soc. Nat. Hist.*, entitled "On a hitherto unrecognised form of blood circulation without capillaries in the organs of Vertebrata." "Sinusoids" is the name proposed for the newly-discovered vessels, which are said to differ in many respects from true capillaries.

The "Descriptive Guide" to the collection of corals now on view at the South London Art Gallery, Peckham Road, Camberwell, may be described as a wonderful "pennyworth." Not only does it contain two excellent photographic plates of corals, but the text is an excellent popular introduction to the study of these beautiful structures. The collection in question is the property of Mr. J. Morgan, of St. Leonards, who has kindly loaned them for public exhibition.

From its last *Report* we are glad to notice that the Felsted School Scientific Society appears in a flourishing condition. Physics and chemistry receive a larger share of attention than is usually the case in school societies, owing, doubtless, to the fact that the president, Mr. A. E. Munby, teaches these subjects in the school. Dr. Charles Hose has kindly offered to present a selection from his Bornean treasures if proper accommodation can be obtained for their display.

"Codium" is the title of the fourth issue of the Liverpool Marine Biological Committee's memoirs. The remarkable branching alga originally described as *Fucus tomentosus*, but now designated *Codium tomentosum*, is one of three British representatives of the group *Codiaceae*, but the only one found within the area treated of in this series of memoirs. Although widely distributed, it occurs within the district only in shallow rock-pools at the south end of the Isle of Man. The plants are perennial, and fruit in winter; the season of fructification apparently extending from November till February. The authors of the memoir have worked out the life-history of the organism so far as their materials admitted of this being done; but there are certain problems connected with the reproduction which require further investigation.

Dr. R. W. Shufeldt contributes a paper on the psychology of fishes to the April number of the *American Naturalist*. In general it may be said that fishes possess excellent visual power, even to the exact discrimination between objects; and there is also reason to believe that they are extremely sensitive to any disturbance of their native element, when such disturbance is within the range of appreciation of their nervous organs. Whether, however, any fish has the extreme sensibility of the leech *Clepsine*, which, when the experiment is conducted with proper precautions, will be conscious of the touch of a needle-point on the surface of the water of the dish in which it is placed, is more than doubtful. The peculiar sensitiveness to teasing exhibited by the fish known as the snowy grouper (*Epinephelus niveatus*) is instanced by the author as a phenomenon requiring special explanation. When much disturbed, this fish displays a spasm, or fit, much resembling the contortions of death, eventually floating belly-upwards, and at the same time changing colour. The author suggests that these movements are for the purpose of warning off predatory fish, which prefer to take their prey in a healthy condition after an exciting chase.

A Preliminary Report on the Klondike Goldfields, Yukon District, Canada, has been published by Mr. R. G. McConnell. (Printed in advance from the Summary Report, Geol. Surv. Canada for 1899, 1900). The rocks consist of stratified and foliated rocks, mostly Palæozoic, and of granites and other eruptive rocks of Tertiary age. Of the older rocks, the Klondike series constitutes the country rock along the productive portions of all the richer creeks. It mainly comprises micaceous schists, greatly crushed and altered, which pass in places into a granitoid rock. Quartz veins are very abundant, and these occasionally contain free gold. The placer deposits have derived their gold from the quartz veins and silicified schists of the district; and it is considered probable that productive veins, or zones of country rock, will eventually be discovered. A fairly full account is given of the placer deposits, so far as they are known, but the author remarks that the work of the prospector will not be completed for many years. The valleys known to be productive in gold are shown on a map.

"Notes on the Fossil Flora of South Gippsland," by Mr. James Stirling, Government geologist, have been published by the Department of Mines, Victoria (1900). The plants, which include ferns, cycads and conifers, were obtained from Jurassic strata. They are illustrated in six plates, which accompany the notes, and which were prepared under the direction of the late Sir Frederick McCoy.

Messrs. Archibald Constable and Co. will publish in a few weeks Mr. W. Worby Beaumont's new and comprehensive work, "Motor Vehicles and Motors: Their Design, Construction and Working by Steam, Oil and Electricity."

Prof. J. A. Ewing's standard work on "Magnetic Induction in Iron and Other Metals" (The *Electrician* Printing and Publishing Co.) has reached a third edition. A chapter has been added on practical magnetic testing, and important advances made since the book was originally published have been taken into consideration.

Messrs. Newman and Guardia, Limited, have just placed a new quarter-plate pocket camera—the "Nydia"—upon the market. The camera is fitted with a special 5½-inch lens, either Zeiss, Wray or Ross make; it carries twelve films or eight plates; when folded it measures only 7¼ × 4¼ × 1¾ inches, and it only weighs, when loaded, 1¾ lbs. Photographers requiring a portable and efficient hand camera at a moderate price should see the "Nydia."

The fourth edition of "Psycho-therapeutics," by Dr. C. Lloyd Tuckey, has been issued by Messrs. Ballière, Tindall and Cox. The third edition was published nearly ten years ago and since that time hypnotism and suggestion have become recognised forms of medical treatment. Dr. Tuckey's work is a useful statement of the development of the system of psycho-therapeutics, both from the theoretical and practical sides, and it will show practitioners what can be accomplished by hypnotic suggestion.

ALTHOUGH a large amount of work has been published upon the physical properties of dilute solutions of single electrolytes, the experimental study of solutions of mixed electrolytes, notwithstanding its great interest from the point of view of the electrolytic theory of dissociation, has not been worked at so extensively. The theoretical discussion of such mixtures leads to a set of equations somewhat difficult to solve; but since Prof. MacGregor, of the Dalhousie College, Halifax, Nova Scotia, showed how to solve these equations by a simple graphical method, systematic researches have been carried on at this college on the properties of such mixed solutions of electrolytes. A recent paper, by Mr. J. Barnes, in the *Transactions* of the Nova Scotian Institute of Science, deals with the depression of the freezing point in salts containing a common ion; and the results show that in the case of mixtures of potassium chloride and sodium chloride, and of sodium chloride and hydrochloric acid, and of all three, it is possible, with the ionisation coefficients obtained by Prof. MacGregor's method, and on the assumption that the molecular depression of an electrolyte in a mixture is the same as it would be in a simple solution of the same total concentration, to predict the depression of the freezing point within the limits of the error involved in observation and calculation.

**THE** additions to the Zoological Society's Gardens during the past week include a Bonnet Monkey (*Macacus sinicus*, ♂) from India, presented by Lady Malcolm, of Poltalloch; a White-crested Tiger Bittern (*Tigrisoma leucolophum*) from West Africa, presented by Mr. W. F. Marshal; four Chaplin Crows (*Corvus capellanus*) from Southern Persia, presented by Mr. B. T. Ffinch; a Cinereous Vulture (*Vultur monachus*), European, presented by Mr. W. E. Found; a Common Boa (*Boa constrictor*) from South America, presented by Mr. F. H. Preston; two Egyptian Foxes (*Canis niloticus*) from North Africa, two Prevost's Squirrels (*Sciurus prevosti*) from Malacca, a Ring-tailed Coati (*Nasua rufa*) from South America, two Porto Rico Pigeons (*Columba squamosa*) from the West Indies, a Sclater's Cassowary (*Casuarius sclateri*), two Red-sided Eclectus (*Eclectus pectoralis*) from New Guinea, four Loggerhead Turtles (*Thassochelys caretta*) from Tropical seas, twelve Elegant Terrapins (*Chrysemys scripta elegans*), seventeen Lesueur's Terrapins (*Malacoclemmys lesueuri*) from North America, twelve Adorned Terrapins (*Chrysemys ornata*) from Central America, seven Reeves's Terrapins (*Damonia reevesi*) from China, deposited; five Hairy Armadillos (*Dasypus villosus*) from La Plata, four Common Indian Starlings (*Sturnus menzbieri*), a Bengal Fox (*Canis bengalensis*) from India, two Meyer's Parrots (*Poeocephalus meyeri*) from South-east Africa, four Australian Sheldrakes (*Tadorna tadornoides*), five —— Wood Swallows (*Artamus sordidus*) from Australia, six Sulphury Tyrants (*Pitangus sulphuratus*), a Black-pointed Teguexin (*Tupinambis nigropunctatus*) from South America, purchased; a Crowned Lemur (*Lemur coronatus*), six Common Wolves (*Canis lupus*), a Llama (*Lama peruana*) born in the Gardens.

## OUR ASTRONOMICAL COLUMN

UNPUBLISHED OBSERVATIONS AT RADCLIFFE OBSERVATORY, 1774–1838.—In a pamphlet containing a reprint of an article in *Monthly Notices*, vol. lx. pp. 265–293, Dr. A. A. Rambaut, Radcliffe observer at Oxford, calls attention to a very valuable collection of astronomical observations which are preserved at the Radcliffe Observatory, but have not been reduced or published. Two of the Oxford astronomers, Profs. Hornsby and Robertson, spent a large amount of labour in reducing Bradley's observations made at Greenwich from 1750–1762, and further continued his work by themselves maintaining a systematic and regular series of observations for sixty-five years, from 1774–1838. These were all made with the instruments supplied by Bird to the Radcliffe Observatory at its installation, consisting of two quadrants each of 8-feet radius, a transit instrument of 8-feet focal length, and a zenith sector of 12-feet focus. The observations have all been methodically copied in a similar form to their printed edition of Bradley's observations, and contain altogether about 130,000 transits and 60,000 zenith distances. Dr. Rambaut states that his staff at present could not undertake the reductions; but, in order to show the extreme importance of the data available, he has made a selection of them, giving the probable errors compared with other observers.

The planets and sun have received considerable attention, there being about 8000 observations of the sun alone, a number little less than that on which Leverrier's tables were founded, and, moreover, covering the period when the corrections to the mean longitude of the sun, as deduced at Greenwich, Paris and Königsberg, are most discordant.

The working list of stars includes about 4870 of those observed by Flamsteed and Bradley, so that direct comparisons could be made in the reductions. Their great value would be specially apparent in the question of proper motions, filling up as they do the long gaps between Bradley and Piazzi, or Bradley and Pond. Specimens of Dr. Rambaut's reductions are given in the paper to show the high degree of accuracy attained by the observations.

MAXIMUM DURATION FOR A TOTAL SOLAR ECLIPSE.—Mr. C. T. Whitmell, president of the Leeds Astronomical Society, recently read a paper showing the results of calculations he had made in the endeavour to ascertain what is the maximum duration possible for a total solar eclipse (*Monthly Notices*, R.A.S., vol. lx. pp. 435–441). After considering the several effects of the varying distances of sun and moon from the earth in determining size of umbra and velocity of shadow, he cites the following five conditions as required for maximum duration of totality:—

(1) The new moon, at or very near a node, must also be at the most favourable perigee possible; (2) the sun must be at apogee; (3) during totality, which should be observed at local noon, the moon's shadow should run along a parallel of latitude, in order that the diurnal movement of the observer may be for the time parallel to the motion of the moon, thereby producing its full effect in detaining him within the umbra; (4) the sun and moon should be in the zenith, so that the umbra may be as large as possible; (5) the observer should be on the equator, so that his linear velocity may be as great as possible.

Of these, owing to the sun and moon *not* moving in the plane of the celestial equator, it is impossible that (4) and (5) can be simultaneously fulfilled; (5) is more favourable than (4).

Taking the moon's horizontal parallax as 61′ 22″,
,, ,, earth's radius as 3963 miles,
,, ,, moon's ,, 1081·5 miles,

and using the present accepted *eclipse* values of the diameters of the sun and moon, the maximum totality will occur near the middle of July, at noon, in geocentric north latitude about 4° 52′, and will last about 7m. 40s., the sun being at apogee with a parallax of 8″·70. This is on the assumption that the declinations of the two bodies are considered practically constant during totality. The author gives the following list of long duration eclipses, calculated by Mr. Crommelin from Oppolzer's data:—

| Date | Duration at noon | Position of noon point | |
|---|---|---|---|
| | | Longitude | Latitude |
| | h. m. | ° | ° |
| 1901 May 18 | 6 41·6 | 97 E. | 2 S. |
| 1919 May 29 | 7 5·9 | 18 W. | 4 N. |
| 1937 June 8 | 7 19·9 | 131 W. | 10 N. |
| 1955 June 20 | 7 24·5 | 117 E. | 15 N. |
| 1973 June 30 | 7 19·6 | 6 E. | 19 N. |
| 1991 July 11 | 7 10·7 | 105 W. | 22 N. |

## THE FRESH-WATER LOCHS OF SCOTLAND.[1]

THE introduction to this paper, published in the *Geographical Journal*, includes the correspondence that passed between the Royal Societies of London and Edinburgh and Her Majesty's Treasury in 1883 and 1884, relative to the survey by a Government Department of some of the inland lakes of Scotland.

The weighty arguments brought to bear upon the Government by these learned societies failed in their object, and the Government declined to undertake the proposed surveys. In these circumstances the authors determined a few years ago to make a systematic survey of all the fresh-water lochs of Scotland, and the present paper is the first instalment in the publication of their results, dealing with a compact series of lakes directly or indirectly connected with the water-supply to the city of Glasgow, viz. Lochs Katrine, Arklet, Achray, Vennachar, Drunkie, Voil, Doine and Lubnaig, which form part of one united drainage system having its outflow by the River Teith.

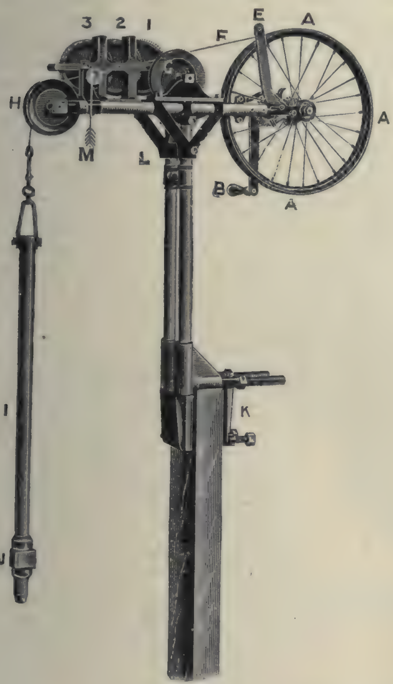

FIG. 1.—F. P. Pullar's sounding machine.

In order to overtake the large amount of work contemplated, involving an immense number of soundings, within a reasonable time, it was necessary to have a portable wire sounding machine adapted for rapid work in small rowing boats. Mr. Pullar designed, and had made, a sounding machine (see Fig. 1), which is described and figured; this apparatus is admirably adapted for the purpose in view, and with it all the soundings in the different lakes were taken.

The total number of soundings recorded in the paper, taken in the eight lochs mentioned, was 2422, the number varying from 775 in the largest (Loch Katrine) to 90 in the smallest (Loch Doine). These soundings were laid down in position on the large scale (six-inch) Ordnance Survey maps, and contour-lines of depth drawn at certain intervals, from which with the aid of the planimeter the cubic mass of water in each loch was calculated. The soundings show that Lochs Katrine, Arklet, Achray, Voil and Doine form each a single basin, while in Lochs Lubnaig, Drunkie and Vennachar the irregularities of the bottom cut up the deep parts of the lochs into separate basins.

The most important of the lakes under consideration is the well-known Loch Katrine, which is eight miles in length, one mile in maximum width, with an area of $4\frac{3}{4}$ square miles. The greatest depth, 495 feet ($82\frac{1}{2}$ fathoms), was found much nearer the eastern than the western end, so that a section drawn down the centre of the loch from west to east (see Fig. 2) shows a gradual increase of depth for nearly four-fifths of the total length, and then a more rapid rise of the bottom towards the eastern end. A section across the loch from north to south (see Fig. 3) shows the deeper part at the point chosen for the section nearer the southern than the northern shore. The mean depth of the loch, *i.e.* the cubic mass of water divided by the area, is 199 feet. The surface of the loch lies at an elevation of 364 feet above the sea, hence a considerable portion of the bottom (over one square mile) falls below the level of the sea; in this respect Loch Katrine differs from all the other lochs treated of. In connection with the water-supply to Glasgow, Loch Katrine was raised four feet above its previous level, and it is now in process of being raised an additional five feet.

Loch Arklet is a small Highland loch situated between Lochs Katrine and Lomond, at an elevation of 455 feet above the sea. It is over a mile in length, nearly half a mile in maximum width, and covers an area of about one-third of a square mile. The greatest depth, 67 feet, was found nearer the western than the eastern end; the mean depth is 24 feet. Loch Arklet at present belongs to the watershed of Loch Lomond, but the Corporation of Glasgow have power to divert its waters into the Loch Katrine watershed, with the view of increasing the supply of water to that city.

Loch Achray is situated between Lochs Katrine and Vennachar, at an elevation of 276 feet above the sea. It receives the outflow from Loch Katrine and flows into Loch Vennachar, the level of which is six feet lower. Loch Achray is about $1\frac{1}{4}$ miles in length, and one-third of a mile in maximum width, covering an area of about one-third of a square mile. The greatest depth, 97 feet, was recorded in two places approximately in the centre of the loch; the mean depth is 36 feet.

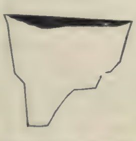

FIG. 3.—Transverse section of Loch Katrine. The black portion shows the true slopes; the outline shows the slopes exaggerated ten times.

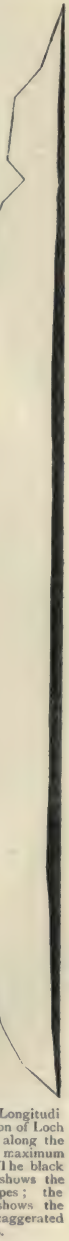

FIG. 2.—Longitudinal section of Loch Katrine along the axis of maximum depth. The black portion shows the true slopes; the outline shows the slopes exaggerated ten times.

Loch Vennachar is about four miles in length, with a maximum breadth of less than three-quarters of a mile, and covers an area of over $1\frac{1}{2}$ square miles. The greatest depth, 111 feet, is situated approximately in the centre of the loch; the mean depth is $42\frac{1}{2}$ feet. Loch Vennachar has been raised five feet nine inches in connection with he Glasgow water-supply, for the purpose of providing compensation water to the River Teith.

---

[1] "A Bathymetrical Survey of the Fresh-water Lochs of Scotland." By Sir John Murray, K.C.B., D.Sc., F.R.S., and Fred. P. Pullar, Esq., F.R.G.S. Part i. The Lochs of the Trossachs and Callander District.

Loch Drunkie is a peculiar irregular little Highland lake, shut in on all sides by high hills, situated, at an elevation of 416 feet above sea-level, a quarter of a mile to the south of Loch Vennachar, into which it flows. It is remarkable in shape, a quadrangular body throwing out three arms in different directions; the maximum length is over a mile, the maximum width of the body over a quarter of a mile, and the area nearly a quarter of a square mile. The greatest depth, 97 feet, was found near the base of the north-eastern arm; the mean depth is 36 feet. Loch Drunkie was raised twenty-five feet in connection with the Glasgow water-supply, for the purpose of supplying compensation water to the River Teith.

Lochs Voil and Doine formed at no distant date a continuous loch, which has been divided into two portions by the material deposited by the rivers. The level of these lochs being fifty feet higher than that of Loch Katrine, it has been suggested that an additional supply of water to Glasgow can be obtained by means of a tunnel from Loch Doine to Loch Katrine through the intervening hills. Loch Voil is over 3½ miles in length, about one-third of a mile in maximum width, and covers an area of nearly nine-tenths of a square mile. The greatest depth, 98 feet, was found towards the western end; the mean depth is 41 feet. Loch Doine is nearly a mile in length, and over a quarter of a mile in maximum breadth, with an area of nearly a quarter of a square mile. The greatest depth, 65 feet, was found towards the eastern end; the mean depth is 33 feet.

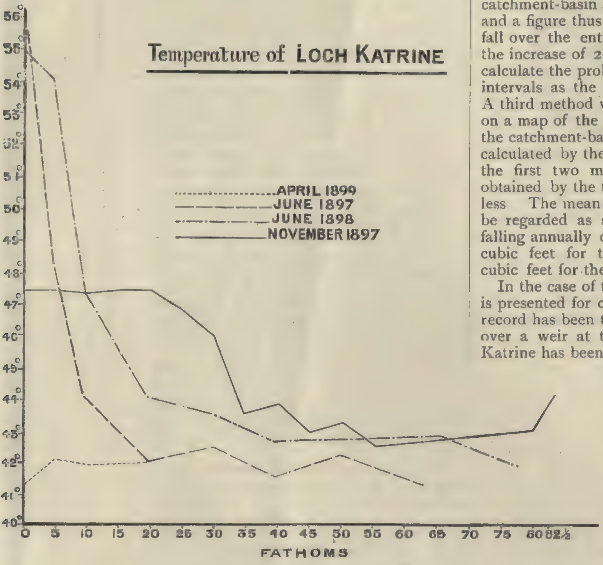

FIG. 4.—Temperature of the water in Loch Katrine.

Loch Lubnaig is one of the most interesting of the lochs under consideration, the configuration of the bottom being much more irregular than in any of the others. It receives the outflow from Lochs Doine and Voil, its level being nine feet lower (405 feet above sea-level). The greatest depth, 146 feet, was found approximately near the centre of the loch; the mean depth is 42¾ feet. The contour-lines of depth do not follow the contour of the loch, hollows and ridges alternate with each other, and in some places comparatively deep water is found close to the shore, while in other places shallow water extends a considerable distance from shore.

The deposits forming on the floor of these lochs are described in detail, and the numerous temperature observations taken at the surface and at various depths down to the bottom (some of which were taken as recently as March 1900) are fully discussed. The serial temperatures taken in Loch Katrine are shown graphically in Fig. 4. The relation between the variation of temperature and the size and depth of the lochs is pointed out, and shows how much more suitable a large deep lake is, as a source of water-supply, than a shallow basin, ensuring a relatively low temperature in summer and a relatively high temperature in winter. Interesting observations were made on the pelagic and other organisms in the various lochs, and on their variation with the season, certain species being obtained in abundance at certain seasons and absent or rare at other seasons.

The amount of rain falling annually on the drainage areas of these lochs was estimated by three methods, the lochs being grouped into two series, viz. Lochs Katrine, Achray, Drunkie and Vennachar, which have their outlet at the eastern end of Loch Vennachar, forming one series; and Lochs Doine, Voil and Lubnaig, which have their outlet at the southern end of Loch Lubnaig, forming the other series. The readings of the rain-gauges at all the observing stations within and near the catchment-basins of these lochs were grouped together into two series corresponding with the two series of lochs indicated, and the average annual rainfall at the average height of the gauges calculated for each series. By the first method, 2½ per cent. of annual rainfall was added for each 100 feet of mean height of the catchment-basin above the average height of the rain-gauges, and a figure thus obtained representing the average annual rainfall over the entire catchment-basin. By the second method, the increase of 2½ per cent. per 100 feet of height was used to calculate the probable annual rainfall at the same heights and intervals as the contour-lines on the Ordnance Survey maps. A third method was afforded by drawing lines of equal rainfall on a map of the district. The total amount of rain falling on the catchment-basins of the two series of lochs indicated was calculated by these three methods, and the results obtained by the first two methods agree very closely, while the results obtained by the third method were in each case considerably less The mean obtained by the three methods may probably be regarded as a close approximation to the amount of rain falling annually on these catchment-basins, viz. 14,100 million cubic feet for the Vennachar catchment, and 14,700 million cubic feet for the Lubnaig catchment.

In the case of the Vennachar catchment a unique opportunity is presented for comparing the outflow with the rainfall, for a record has been taken twice a day of the depth of water flowing over a weir at the east end of Loch Vennachar since Loch Katrine has been made use of by the Glasgow Corporation as the source of the water-supply to that city. The readings of the depth of the outflowing water during the year 1869 have been calculated out, and the outflow for that year has been estimated at 9572 million cubic feet. The quantity of water supplied to Glasgow during the year 1869 is estimated at 1660 million cubic feet. There is thus an excess of rainfall, according to the mean of the three methods, over the overflow of 2860 million cubic feet. This difference must be accounted for by absorption, evaporation and loss of water by underground channels. The readings of the outflow for a series of twenty-five years or more would be a far more satisfactory basis for calculation than a single year's readings (and the year 1869 was not an average, but a very dry year), and it would be very interesting to have the average annual outflow calculated over the whole period during which the record has been kept, in the same way as the mean annual rainfall is calculated for a particular station. Records of the rainfall at high elevations in different parts of the catchment-basins would also be desirable in comparing the average annual rainfall with the average annual outflow.

Appended to the paper is an account of the geology of the district by Messrs. B. N. Peach, F.R.S., and J. Horne, F.R.S., based on materials collected during the Geological Survey of that region, and published by permission of Sir Archibald Geikie, the Director-General. A brief sketch is given of the geological structure of the area embracing the various lochs, which has an important bearing on the question of the evolution of the valley-system. It is shown that, along the Highland border, there is a great development of conglomerates, grits and greywackes, belonging partly to the crystalline schists and partly to the Old Red Sandstone. These strata, being vertical or nearly so, would be much less easily eroded than the gently inclined schistose rocks lying to the north-west. Such an arrangement would naturally lead to the formation of narrow and comparatively flat-bottomed valleys behind rocky gorges, the latter being cut through the vertical beds of hard grit and conglomerate along the Highland border. Evidence is adduced to show how this remarkable structure likewise contributed to the erosion of rock basins during the glacial period. The glacial phenomena of the region are reviewed, which indicate at least two periods of glaciation; one, when the ice-shed lay to the north of the area under consideration, when the ice-movement was independent of the existing valley-system, and when even the highest mountains were overridden by the ice. This great development was followed by a period of local glaciation, when the glaciers were confined mainly to the existing valleys. Lastly, the soundings of the various lochs are viewed in relation to the geological history of the area, and with reference to the question of the origin of the various lakes. It is shown that some of the lochs are typical examples of rock basins, that in some instances the deepest soundings occur in front of the rocky barriers at or near their outlets. Reference is made to all the important faults traversing the region, which have led to the more rapid disintegration of the materials, but though they have in certain cases produced modifications of the floors of the lakes, they cannot account for the excavation of the rock basins. The soundings of Loch Lubnaig reveal the striking fact that one of the deep basins in that lake lies on the upthrow side of the most powerful fault traversing the crystalline schists of that region. Messrs. Peach and Horne believe that the soundings of the various lakes in the basin of the Teith above Callander furnish strong evidence in support of Ramsay's theory of their excavation by ice-action.

The paper is illustrated by seven coloured maps, the first three showing on a small scale the orography and drainage areas, the surface geology and the rainfall of the district, the other four showing on a larger scale the bathymetry of the various lochs and the relief of the surrounding country. There are also numerous woodcuts, some of which are reproduced in this review.

## IRON AND STEEL INSTITUTE.

THE annual meeting of the Iron and Steel Institute was held on Wednesday and Thursday, May 9 and 10, in the hall of the Institution of Civil Engineers, under the presidency of Sir William Roberts-Austen, K.C.B., F.R.S. The attendance of members was larger than at any previous gathering. The report of the council, which was read by the secretary, Mr. Bennett H. Brough, showed that the Institute is in a flourishing condition. The receipts last year were greater than in any previous year, 110 new members were added to the roll, the supply of original papers was well maintained, and a Royal Charter of Incorporation had been granted. After the usual formal business, the president presented the Bessemer gold medal for 1900 to Mr. Henri de Wendel, the eminent French metallurgist, in recognition of his great services to metallurgy in developing the iron-ore resources of French and German Lorraine. Mr. de Wendel having expressed his appreciation of the honour conferred upon him, Mr. Stead announced that he had decided to postpone the reading of his paper until the autumn meeting in Paris.

Mr. J. Riley then described the various attempts that have been made to use fluid metal in the open-hearth furnace. The results he obtained at Wishaw, in 1898, were encouraging, and experience over a considerable period show that great advantages are derived from the adoption of this method. The best future open-hearth practice, he considers, will include the use of fluid metal direct from the blast furnaces.

The next paper read was one of most conspicuous novelty, by Mr. B. Talbot, on the open-hearth continuous steel process. This process was introduced at the Pencoyd steelworks in Pennsylvania. The furnace used is a basic-lined tilting furnace of seventy-five tons capacity. Many thousands of tons of steel have been made by this method with very satisfactory results, all grades of steel having been produced. The cost and delay in charging cold material is avoided. There is a saving in fuel in charging molten pig iron. The demand for a large supply of good scrap is dispensed with. A regular supply of steel in any desired quantity and at frequent intervals is insured. There is an increased output, an increased yield, and a saving in repairs and in labour charges. At the same time it is possible to use very large furnaces, with consequent reduction in cost of production, without the necessity for very large cranes and ladles. A long discussion followed the reading of the paper, the opinion being general that the process is an important advance in open-hearth steel practice.

Mr. A. Greiner gave an account of the results obtained at the Cockerill works, Belgium, with the first blowing-engine worked by blast-furnace gas ever employed in any ironworks. This 600 horse-power engine has been running since November 20 last with unpurified gas taken from the Seraing blast-furnaces.

Baron H. von Jüptner submitted a further instalment of his researches on the theory of solution of iron and steel. He discussed the application of the laws of chemical mechanics in the case of iron carbon alloys, and showed what an important bearing thermo-chemistry possesses for a knowledge of the constitution of the alloys of iron and their alterations of state.

The meeting then adjourned until May 10, when Mr. C. Dellwik dealt with the manufacture and application of water-gas, describing the production of the gas by means of a simple apparatus with a degree of economy surpassing that of other less valuable gas. Whilst in the old processes the gas leaving the generator during the blow contains principally carbon monoxide and nitrogen, in the author's process it consists chiefly of carbon dioxide and nitrogen.

The subject of utilising blast-furnace slag is a fruitful source of inquiry, and a recent important development was dealt with by Mr. C. von Schwarz. This is a successful method of manufacturing cement from blast-furnace slag, recently employed in Germany and Belgium. The cement thus made obtains a higher price in the market than ordinary Portland cement.

Mr. L. F. Gjers and Mr. J. H. Harrison described an apparatus for equalising the varying temperatures of hot blast. Hitherto the hot blast has been allowed to enter the furnace as it left the stove, and in order to obviate the interference with the steady working of the furnace, the authors have devised an apparatus consisting practically of another small stove with a central division wall. It is filled with chequer work; and the hot blast, entering at one side of varying temperature, is delivered out at the other side at an even mean temperature.

The form of ingot that would seem to be the most natural for the manufacture of a gun-tube or a propeller shaft is one with a circular section. Mr. F. J. R. Carulla, however, pointed out the drawbacks of this form, and showed that a polygonal ingot with concave sides answers the required conditions.

Mr. H. K. Scott contributed a paper on manganese ore deposits and mining in Brazil, giving a detailed account of the geological structure of the deposits, and of the economic development of the industry.

After the usual votes of thanks to the Institution of Civil Engineers, proposed by Sir John Alleyne, Bart., and to the president for his conduct in the chair, proposed by Mr. Carnegie, the proceedings terminated. Incidentally, Mr. Carnegie announced his intention of founding a scholarship in connection with the Iron and Steel Institute for the advancement of research in connection with iron and steel.

## THE ROYAL SOCIETY CONVERSAZIONE.

THE general opinion of the scientific company at the Royal Society on Wednesday, May 9, on the occasion of the first of the two soirées held annually, was that novel and striking exhibits were not so numerous as in some exhibitions of previous years. The following were among the most noteworthy exhibits:—

Mr. Richard Kerr showed a clock controlled at a distance by wireless telegraphy of the Hertzian wave system. Mr. J. Wimshurst, F.R.S., exhibited an influence machine, constructed with twelve plates of vulcanite. Prof. Silvanus P. Thompson, F.R.S., showed some pretty electromagnetic experiments, one being the converse of De La Rive's experiment, using floating magnet instead of floating battery, and others showing new varieties of the De La Rive experiment (see p. 71). Prof. Minchin, F.R.S., showed that luminous flashes could be induced in a helium tube by Hertz waves.

An electric micrometer was shown by Mr. P. E. Shaw. The instrument was designed primarily to measure the small movements of a telephone diaphragm. A screw abuts on a system of three levers, set up on a strong wooden frame. By turning the screw, the far end of the levers moves to and fro through distances which can be controlled and measured. This end of the levers carries a rod, and the diaphragm a small plate, both of iridio-platinum; if these two surfaces touch one another, a flow of a small amount of electricity occurs, producing a sound in a telephone held by the observer; at the same time he reads by a telescope a graduated circular scale fixed on the screw. Since the screw and levers can be moved at will by the observer, he can, by this contact method, find the position of the diaphragm, and follow its movements. Precautions against vibrations are taken by having indiarubber suspensions, and against temperature changes by covering the working parts with boxes wrapped in felt. Movements as small as $\frac{1}{200}$th of a wavelength of sodium light have been measured by this apparatus.

Mr. Killingworth Hedges exhibited jointing boxes and aigrettes used in the rearrangement of the lightning conductors of St. Paul's Cathedral. The original system for the protection of the Cathedral from lightning was installed under the advice of the Royal Society in about 1756. This was replaced in 1872 by what was then considered the most improved method, when the unsoldered joints were found to be very defective; in some cases they were quite loose; also the earths, originally made by laying the cable in a drain which had become disused, were in some cases insulated from the ground. New earths have been substituted. The method adopted to protect the structure unites the old system and the new cables to a horizontal conductor run on the top of the parapet, entirely round the building; to this copper aigrettes as shown are teed at intervals.

Other electrical exhibits were models illustrating leakage from electric tramways, shown by Mr. A. P. Trotter, and improved forms of standard resistance coils made by the Cambridge Scientific Instrument Co., Ltd.

Dr. Isaac Roberts, F.R.S., exhibited his magnificent volume of photographs of stars, star-clusters and nebulæ, recently reviewed in NATURE (vol. lxi. p. 533). The volume contains seventy-two photographs, which have been enlarged by mechanical processes from the original negatives, and they furnish evidence of the evolution of stellar systems from nebulous matter as seen in the convolutions of spiral nebulæ. They also furnish a foundation for the inference that the system of the *Milky Way* is not unlimited in extent, and that the numerous aggregations of stars, seen in lines and curves in the stellar regions, indicate their development from spiral nebulæ.

Mr. Thomas Thorp exhibited some of his grating films and their application to diffraction colour photography, on Prof. Wood's principle. Dr. Downing, F.R.S., exhibited maps illustrating the track of the total eclipse of the sun of May 28.

Mr. W. A. Shenstone, F.R.S., and Mr. H. G. Lacell showed a quantity of non-splintering silica, suitable for use in the oxy-gas flame. The method of converting this into tubes and other forms of apparatus, as recently described in NATURE (May 3), was demonstrated practically, together with experiments to illustrate the behaviour of vitreous silica under sudden and great changes of temperature. The following apparatus, constructed of silica, was also exhibited. A long tube for use with a platinum thermometer; a mercury thermometer; bulbs and stems for thermometers; a Giessler tube; a small distilling tube; and rods and tubes of various sizes for various purposes.

Some examples of leadless glazed ware were shown by Dr. T. E. Thorpe, F.R.S.

Mr. H. B. Hartley and Mr. H. L. Bowman gave a demonstration of the properties of crystals yielding doubly-refracting liquids on fusion. Certain crystalline organic compounds, viz. *p*-Azoxyanisol, *p*-Azoxyphenetol, and Cholesteryl benzoate, have been found by Prof. Lehmann, of Carlsruhe, to give on melting (at temperatures of 116°, 134° and 145° respectively) liquids possessing the properties of double-refraction and dichroism, even under conditions in which a state of strain is impossible. When these anisotropic liquids are further heated, they change at definite temperatures of transition (134°, 165° and 178° respectively) into ordinary isotropic liquids. The intermediate bodies have been called "liquid crystals," for, although the evidence of their elasticity, viscosity, and dielectric capacity shows them to be undoubtedly liquids, yet nevertheless they possess, like crystals, both double refraction and dichroism.

Specimens from the reefs of Funafuti were exhibited by Prof. J. W. Judd, C.B., F.R.S., on behalf of the Coral-Reef Committee of the Royal Society. The exhibits included:—(1) Specimens illustrating the rate of growth of corals and calcareous algæ from the reefs of Funafuti. Experiments made by Mr. A. E. Finckh, of Sydney, who in 1898 carried the boring made by Prof. T. E. David in the previous year from the depth of 698 ft. to 1114 ft., have thrown much new light upon this important question. Specimens illustrating these experiments are exhibited. (2) New and interesting forms of Foraminifera, which have been described by Mr. F. Chapman. These include:—(*a*) *Cycloclypens*, a genus previously regarded as being very rare, but now shown to exist abundantly at Funafuti. The two species formerly described are now shown to be dimorphic forms of the same organism. (*b*) A curious form of *Polytrema*, which occurs encrusting various objects in alternate layers with the marine alga *Lithothamnion*, thus forming loose nodules. (*c*) The newly-described *Haddonia*, first obtained from Torres Straits, &c.

Prof. H. G. Seeley, F.R.S., showed drawings of restorations of Dimorphodon. The drawings, of the natural size, are based upon fossil remains from the Lias, in the British Museum. They represent the skeleton as in the quadruped and biped positions; and show the contours of the body at rest, walking, and preparing for flight, to illustrate proportions of the skeleton. Dr. C. I. Forsyth-Major exhibited remains of extinct gigantic and lesser lemurs from Madagascar, and living forms for comparison. Some beautiful examples of chalk fossils were exhibited by Dr. Arthur W. Rowe.

Dr. Manson exhibited longitudinal sections of filariated mosquitoes (*Culex ciliaris*), showing that *Filaria nocturna*, like the malaria parasite, leaves its mosquito host *viâ* the proboscis.

A collection of living marine worms (Annelids) from the neighbourhood of Plymouth, designed to illustrate, as far as possible, the prominent features in the habits of life of the different types of this class of animals, and such modifications of form as are related thereto, formed the exhibit of the Marine Biological Association.

Prof. E. Ray Lankester, F.R.S., on behalf of the Archæological Survey of the Egypt Exploration Fund, showed reproductions of paintings and sculptures in tombs of Ancient Egypt, representing domestic and wild animals and birds. The tombs of Ancient Egypt contain abundant representations of animal life. In spite of the artists' ignorance of perspective and occasional faulty colouring, the outlines are rendered with remarkable fidelity to nature, often enabling the species to be identified. Among domestic animals, the dogs are perhaps the most interesting, as showing that extreme development of various breeds had already taken place. The monuments from which the drawings exhibited were copied are of two periods:—(1) Tombs at Beni Hasan, of the XIIth Dynasty (*circa* 2000 B.C.); (2) the Tomb of Ptah-hetep at Saqqareh, of the Vth Dynasty (*circa* 3000-2500 B.C.).

Prof. A. C. Haddon, F.R.S., showed specimens illustrating the decorative art of the Sea Dayaks of Sarawak. The carved and painted designs of the Dayak men are entirely different from the woven and embroidered patterns made by the women. The former are chiefly plant derivatives, while the latter are mainly greatly modified animal forms. The significance of the distinction and the real meaning of the patterns themselves are not yet elucidated. The method by which the women make the patterns in their woven fabrics was also illustrated. The warp is stretched on a frame, and numerous strands are tied tightly with strips of leaves; the whole is removed and then submerged in a dye. The lashing is then undone, and the tied-up portions are found to be undyed. The whole process is repeated if a three-colour pattern is required.

Ethnographical objects from Malay Peninsula (Malay and Sakai) were shown by Mr. W. W. Skeat. The phonographic records of songs of the Pangan tribe, a wild aboriginal tribe of Negrito stock, received much attention.

A collection of anthropometric instruments was shown by Dr. J. G. Garson.

The Royal Geographical Society exhibited a section cut from the tree on Lake Bangweulu, Central Africa, under which Livingstone's heart was buried, and containing the inscription carved by his native followers.

In the course of the evening, short discourses and demonstrations were given by Sir Andrew Noble, K.C.B., F.R.S., on modern explosives; Dr. Arthur W. Rowe, on the photomicrography of chalk fossils by reflected light; and Mr. F. Enock, on photographs from living insects, showing the metamorphoses of one of the Odonata.

## *UNIVERSITY AND EDUCATIONAL INTELLIGENCE.*

CAMBRIDGE.—The King of Sweden and Norway was on Monday admitted by the Chancellor to the honorary degree of LL.D. The ceremony was witnessed by a vast assembly, and the King gave much pleasure by his gracious bearing and evident interest in the proceedings.

The General Board are about to appoint a lecturer in experimental physics in succession to Mr. W. N. Shaw. Applications are to be sent to the Vice-Chancellor by May 19.

The Master of Downing and Dr. Barclay-Smith announce a course of instruction in practical histology, to be given during the long vacation, beginning on July 7.

The trustees of the late Miss R. F. Squire have offered the University a sum of about 13,500*l.* for the erection of a law library in connection with the new law school, and adjoining the Sedgwick Memorial Museum. This timely benefaction will probably facilitate the speedy erection of the the Botanical and Medical Schools, plans for which are now under the consideration of the Senate.

The proposal to establish a special examination in the sciences bearing on agriculture, as a qualification for the ordinary B.A. degree, was favourably received in the Senate on May 10, and a grace for its adoption has been sanctioned by the council.

An examination for minor scholarships in Natural Science will be held at Downing College in March 1901. Application for particulars should be made to the tutor.

A VERY satisfactory side of technical education is the work carried on in the lecture-rooms and laboratories of University Colleges, in connection with Technical Instruction Committees. Two short courses of evening lectures to teachers, just arranged by the Technical Instruction Committee of Liverpool with Prof. Oliver Lodge and Prof. Herdman, are instances in point. The lectures deal with some recent developments of physical and natural science, Prof. Lodge taking for his subject "Electric Vibrations," and Prof. Herdman "Oceanography." The lectures are free to teachers who can give evidence that they are able to profit by them.

VISITS to museums, and outdoor lessons, are counted as school attendances by the Board of Education, with the result that they are now given a definite place in the scheme of instruction of many schools. In a similar way, the National Zoological Park at Washington is used to place great object-lessons before the hundreds of thousands of visitors to the national capital from all parts of the United States. The pupils in the public schools of Washington benefit greatly by these opportunities. It has become a part of their routine to visit, under the care of a teacher, the Smithsonian Institution and National Museum buildings, as well as the park; while those outside the city benefit indirectly through the numerous excursions of teachers, and the stimulus and suggestion they may thus receive.

Two new buildings in connection with the Yorkshire College, Leeds, to be devoted to the development of clothworkers' research and dyeing, &c., were formally opened, on Friday last, by the Master of the Clothworkers' Company, Mr. A. C. Cronin. Principal Bodington, of the Yorkshire College, the professors and students, and mayors of various boroughs, also attended on the occasion. It was explained that it was intended to raise the tone of dyeing, and that the outlay on the extensions is likely to yield a tenfold return. Mr. Cronin, in declaring the new buildings open, expressed a hope that increased knowledge in the industries would be the result of these extensions. At a luncheon which followed, in responding to the toast of "The Clothworkers' Company," he said it was the intention of the Company that the Yorkshire College should become the first and most complete example of a textile and dyeing school not only in Europe, but in the world. There is now hardly any manufacturing town of any size in Yorkshire which has not its technical school or institute, and with which the Clothworkers' Company has not been or is not still connected.

THE medical school of the future was the subject of an address delivered before the fifth triennial Congress of American Physicians and Surgeons, on May 2, by the president, Prof. H. P. Bowditch, of Harvard. According to Prof. Bowditch, we may expect that a medical school of the first rank will, in the immediate future, be organised and administered somewhat as follows:—(1) It will be connected with a university, but will be so far independent of university control that the faculty will practically decide all questions relating to methods of instruction and the personnel of the teaching body. (2) It will offer advanced instruction in every department of medicine, and will therefore necessarily adopt an elective system of some sort, since the amount of instruction provided will be far more than any one student can follow. (3) The laboratory method of instruction will be greatly extended, and students will be trained to get their knowledge, as far as possible, by the direct study of nature, but the didactic lecture, though reduced in importance, will not be displaced from its position as an educational agency. (4) The work of the students will probably be so arranged that their attention will be concentrated upon one principal subject at a time, and these subjects will follow each other in a natural order. (5) Examinations will be so conducted as to afford a test of both the faithfulness with which a student performs his daily work and of his permanent acquisition of medical knowledge fitting him to practise his profession.

THE first official ceremony of the University of London in the new home at South Kensington was the presentation of degrees by the Prince of Wales on Wednesday, May 9. The University has thus entered upon a new phase of its career. As the Chancellor of the University remarked in his address, nothing has been more striking within the last few years than the progress of new universities in different parts of the country. The University of Wales, of which the Prince of Wales is Chancellor, has been founded, and, although very young, it is already making notable progress and will ultimately be a great success. Besides this, there is the Victoria University, of which Lord Spencer is Chancellor, and which has made remarkable progress; and also the completely new University of Birmingham. What does all this mean? It means that the country is stirred up on the subject of education; and among all classes and places there is a greater sense of the importance of it than ever there has been before. As to the University of London, the Chancellor quoted figures to show the great progress which has taken place, and made special reference to the great stimulus to the improvement of the education of women throughout the country arising out of the action of the University in obtaining a supplementary charter to enable women to be admitted to the examinations. Up to the present time the University has been only an examining body. It has by its examinations done a good work for the education of the people, and it has set an example which has had a very important effect upon all the schools throughout the country. But it is now a teaching University, and with its large list of faculties its work will be very widespread. The Prince of Wales then made a few remarks, in the course of which he said: "No one wishes more sincerely than I do happiness and prosperity to this University; and from all that we have heard from the Chancellor I think the University is in a fair way of becoming one of the greatest importance, and one that will hold its own, no doubt, with many of the others which are of more ancient origin. I am glad to think that, as the result of somewhat difficult, and I may say somewhat delicate, negotiations, the London University has now found a home in this large building, better known as the Imperial Institute, in which, as you all know, I take a deep interest. We are very grateful to Her Majesty's Government for all they have done, and for having facilitated the arrangements which I hope are now complete. It only rests with me to express the fervent wish that the London University will not regret having come to a more distant part of London, and that they will find that they have ample room for all their requirements in this University."—Sir Michael Foster, M.P., then addressed those who had received awards at the hands of the Chancellor. He reminded them that the value of the degree was not in the degree itself, but in the labour which had led up to it. The degree might be the guinea stamp, but it was the work and the mental discipline which was the real gold.

## *SCIENTIFIC SERIALS.*

*Bulletin of the American Mathematical Society*, April.—Prof. F. N. Cole summarises the *Proceedings* of the February meeting of the Society, and abstracts a few of the papers communicated. The bye-laws were revised. By this amendment it is provided that the ex-presidents shall be life-members of the council, and that the presidential term of office shall be extended to two years.—Prof. J. Pierpont gives an interesting account of the summer meeting of the Deutsche Mathematiker-Vereinigung held at Munich in September of last year.—Some theorems concerning linear differential equations of the second order is an abstract by Prof. M. Bôcher of certain results which he communicated at the February meeting (see *supra*).—A paper by Dr. M. B. Porter, read at the same meeting, is entitled "A note on the enumeration of the roots of the hypergeometric series between zero and one." It is a continuation of a note published in the May (1897) number of the *Bulletin*.—Dr. J. Sommer reviews Hilbert's "Grundlagen der Geometrie," and Prof. E. O. Lovett does the same for Kœnig's "Leçons de Cinématique."—The longer papers read before the Society will, we presume, be printed in the new *Transactions*.—The notes are very full, and there is a fair list of publications.

*Bulletin de l'Académie des Sciences de St. Pétersbourg*, vol. vii. No. 3.—On the rotation of Jupiter and his spots, by Th. Bredikhin. An analysis of the observations made by the author himself at Moscow, and of some later observations at Pulkova. A comparison of the times of rotation of spots situated in the same latitudes shows that some of them are formed in the lower, and some in the higher strata of Jupiter's atmosphere. Prof. Joukovsky's formulæ hold good as a rule; but a more careful discussion shows that the law of friction must be altered; the latter is proportional to the square or even to a higher degree of velocity. But it would be extremely difficult to make a theoretical discussion if the law be altered in this sense.—The scientific results of the Black Sea expedition, by A. Ostroumov: iii. Fishes of the Sea of Azov.—Materials for the hydrology of the White Sea and the Murman Sea (Arctic Ocean along the Norman coast), by N. Knipovitch: i. Lists of the Observations.

Vol. vii. No. 4.—The series of Jean Bernoulli, by N. Sonin.—New researches into the spectrum of $\beta$ Lyræ and $\eta$ Aquilæ, by A. Belopolsky. These new researches were made with the aid of the 30-in. refractor of Pulkova. The spectroscopic velocities of $\eta$ Aquilæ showed a periodicity very near to the periodicity of the variations of magnitude, *i.e.* 7 days 4 hours, and it was possible to calculate its orbit. Similarly, as for $\delta$ Cephei, it was proved that the changes of brilliancy in $\eta$ Aquilæ cannot be explained by eclipses of the star. As regards $\beta$ Lyræ, the former suppositions of the author are now fully confirmed. This star represents a system of two bodies, having at any instant opposite spectroscopic velocities, and one of the two bodies eclipses the other during their revolutions.—Preliminary communication on applications of Rykatschew's method for studying the relations between rainfall and height of water in rivers, by Dr. Harry Gravelius.—The third international balloon ascents of May 1, 1897, by Ed. Stelling.—Observations of the satellites of Mars with the 30 in. refractor at Pulkova, by F. Renz; and on the photographs of Mars, by S. Kostinsky.

Vol. vii. No. 5.—On the changes of pressure under the piston of the air-pump, by Prince Galitzin. Theoretical discussion is compared with direct observation.—Some remarks on the sensibility of the eye, by the same author.—Abstract from the yearly report for 1896 of the Central Physical Observatory, by M. Rykatschew.—On the excretory organs of *Ascaris megalocephala*, by S. Metalnikoff.—On the routes of the cyclones over Russia in 1890–92, preliminary communication, by P. Rybkin.

## *SOCIETIES AND ACADEMIES.*

### LONDON.

**Physical Society**, May 11.—Prof. O. J. Lodge, F.R.S., President, in the chair.—A discussion of Prof. Lodge's paper on the controversy concerning Volta's contact force was commenced by Prof. Armstrong. Prof. Armstrong expressed his indebtedness to the president for putting forth clearly what we are trying to understand, and said that it was hardly time for chemists to enter the discussion when physicists themselves differed. There has apparently been a change in front since the time when the effect was supposed to be due either to (1) chemical action between the metals, or (2) oxidation. Prof. Lodge's view is intermediate, but approximates to the second. Prof. Armstrong said that from a practical point the existence of the effect was unknown, because sufficient precautions had never been taken to prevent chemical action. He urged the continuance of experiments similar to those carried out by Mr. Spiers, and stated that modern ideas of chemistry were favourable to the view which Prof. Lodge had taken up with regard to the Volta effect.—Mr. Glazebrook made some remarks upon the meaning of the term E which occurs in the expression for the Peltier effect at the junction of two metals. If we confine our attention to an infinitesimal cycle at the junction of two metals at slightly different temperatures, we get the equation for the Peltier effect in which E is the potential difference at the point considered. If then, assuming reversibility, we sum up all the infinitesimal cycles round a circuit and get a finite cycle, the E.M.F. of the circuit is a function of the two temperatures between which it is working. Differentiating with respect to temperature the total E.M.F. of the circuit, we get an equation which applies to the circuit as a whole, and in which E is the total E.M.F. round the circuit. Mr. Price asked if any critical experiment could be suggested to settle the question.—Dr. Lehfeldt called attention to some experiments which had been performed to measure the potential difference between an electrolyte and a gas. The electrolytes considered were chiefly aqueous solutions, and the potential differences observed varied largely. The surface tensions of the liquids were measured, and it was shown that the variations in the potential difference were very similar to those in surface tension. This suggests, in the case of electrolytes, true physical surface effects, and not chemical action.—The chairman remarked that Dr. Lehfeldt evidently looked upon the metal-ether boundary as being the effective one. The experimental evidence is not sufficient to say exactly which is the effective contact, but it seems to show that the metal-ether effect is of the same order of magnitude as the oxygen layer effect. According to Helmholtz they ought to be related, and they apparently are.—The chairman then read a paper, by Mr. J. B. Tayler, on the heat of formation of alloys. Experiments have been made upon alloys of lead with tin, bismuth and zinc, and of zinc with tin and mercury. The method employed consisted in dissolving (1) the alloy, and (2) the corresponding mixture of metals in mercury, and measuring the heat of solution in each case. On the assumption that the solutions obtained are identical, the difference between the heat of solution of the mixture and that of the alloy is the heat of formation of the latter. The calorimeter was a thin glass tube silvered on the outside and supported by a stouter tube silvered on the inside. Suitable arrangements were adopted for the introduction of the metals or alloys, which were used in the form of filings. Solution was often complete in less than a minute, and rarely took more than two minutes and a half. The alloys first experimented upon contained their constituents in equivalent proportions, and the heats of formation were found to be small in comparison with those found for brass by Galt and Baker. It was thought that only a small percentage of the atoms present had entered into definite chemical combination, and that more reliable results would be obtained by dissolving a small quantity of one metal in an excess of the other, and calculating from the experimental results the heat of formation of the gramme-molecular weight of compound upon the supposition that the whole of the small quantity of metal had entered into chemical combination by the exercise of its normal valency. Using the numbers so obtained to find, by Kelvin's theory, the potential difference which should exist between the metals concerned when put in contact, results were arrived at which agreed neither with the Volta effect nor the Peltier effect, but which were considerably nearer the former than the latter. A paper on the want of uniformity in the action of copper-zinc alloys on nitric acid was read by Dr. J. H. Gladstone. Experiments have been made by dissolving copper-zinc alloys in nitric acid, following the method of Dr. Galt, and adopting the precautions mentioned by him. The reaction between nitric acid and these metals or alloys is very complicated, and there is a difference between the products in the case of an alloy and in the case of the equivalent mixed metals. The gases evolved being small in the experiments performed, attention was directed to the determination of the substances remaining in solution, *i.e.* the nitrous acid and ammonia. The alloys gave much more nitrous acid and less ammonia—in fact, two of the alloys employed produced no ammonia. Discrepancies in results may be due to the fact that the zinc and copper in contact form a zinc-copper couple which in the presence of acid sets up a vigorous action and produces a different evolution of heat. Difficulties arise in the investigation because the alloys used may not be definite chemical compounds, but mixtures of two or more alloys with uncombined zinc and copper. The alloy with 38·38 per cent. of copper appears to be fairly uniform. Different observers disagree as to the amount of heat produced by any reaction, but the excess of calories in a zinc reaction over those in a copper reaction appears to be fairly constant. Starting with 640 calories, the value, according to Galt, when copper is dissolved in nitric acid of sp. gr. 1·360, we should have 1357 calories when zinc is dissolved, provided the chemical action is the same in each case. All the calorimetrical results from the different specimens of alloys would theoretically lie upon the straight line drawn between 604 and 1357. This is practically so from pure copper to the copper 70 per cent. alloy, but beyond that there is less heat produced than that indicated by the straight line law, the maximum deviation lying at about copper 37 per cent. The specimen containing 38·38 per cent. copper, which is not far from the alloy $CuZn_2$, shows a loss of 32 calories. The only way in which this deficit can be accounted for is by supposing that the action of this alloy on nitric acid produces a larger quantity of nitric oxide than in the case of pure copper. But, allowing full force to this argument, it cannot account for as much as 10 calories of the deficit. There is, therefore, a residual deficit as yet unaccounted for on chemical grounds. The author states that it is desirable that experiments should be conducted on the zinc-copper alloys with solvents which give a simpler chemical action than that produced by nitric acid. The chairman pointed out that the results obtained by Galt for an alloy which appeared to be a chemical compound, were in close agreement with what would be expected from the existence of the Volta contact force. Prof. Armstrong said that the action of nitric acid on brass or zinc and copper was a function of the quantity of acid present, its strength, the temperature and the pressure; and that, therefore, it was unsatisfactory to conduct experiments using nitric acid as a solvent. He suggested the use of a solution of bromine in which finely-powdered zinc, copper and brass are easily soluble with a simple chemical reaction. Mr. Tomlinson pointed out that it was impossible to use the ordinary formula for the calculation of the Volta effect from the heat of formation of alloys, unless we know exactly the chemical composition of the alloy which is produced. Mr. W. R. Cooper, referring to Mr. Tayler's paper, said it was difficult to see that anything could be proved by the application of the Kelvin theory to a metallic contact, unless there is ground for believing that some particular alloy of fixed composition is always formed. There is also a further difficulty in converting heat of formation into E.M.F. in cases where the metals have different valencies, for there is no reason why one valency should be selected rather than the other. Referring to Dr. Gladstone's paper, Mr. Cooper said that it was possible that the difference in the reducing powers of mixtures and alloys might be due to local action, which would be more pronounced in the case of alloys. More hydrogen would be evolved, and the reduction would be more complete.—Prof. S. P. Thompson then showed an electromagnetic experiment. A circular coil capable of carrying a strong current was placed with its axis horizontal in a tank of water. Into the tank were also placed some small magnets in sealed glass tubes so adjusted as to have a density approximately equal to that of water. The magnets just floated or just sank. On running a current through the coil it was possible to "fish" for the magnets, which, acted upon by the magnetic field, immediately made their way to the coil. When the current was carefully reversed upon the approach of a magnet, repulsion instead of attraction took place, and the magnet retreated. In general, however, reversal of the current produced reversed polarity in the magnet, and attraction still persisted.—The Society then adjourned until May 25.

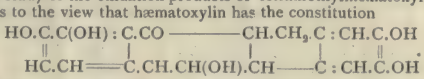
**Chemical Society,** May 3.—Prof. T. E. Thorpe, President, in the chair.—The following papers were read:—The substituted nitrogen chlorides and nitrogen bromides derived from ortho- and para-acet-toluide, by F. D. Chattaway and K. J. P. Orton. Hypochlorous and hypobromous acids convert ortho- and para-acet-toluide into substituted nitrogen chlorides and bromides, which readily undergo transformation into the isomeric substituted toluides.—The estimation of hypoiodites and iodates; and the reaction of iodine monochloride with alkalis, by K. J. P. Orton and W. L. Blackman. The authors' method of estimating hypoiodites is based on the oxidation of sodium arsenite by hypoiodites, but not by iodates. The initial reaction of iodine monochloride and alkalis is represented by the equation $ICl + 2MOH = MIO + MCl + H_2O$; conversion of the metallic hypoiodite into iodide and iodate becomes complete after twenty-four hours.—Products of the action of sulphur dioxide on ammonia, by E. Divers. Amongst the products of spontaneous decomposition of ammonium amidosulphite is found a substance of acid properties to which the author assigns the constitution

$$\mathrm{NH}\left\langle\begin{array}{l}\mathrm{SO_2.O}\\ \qquad\ \,| \\ \mathrm{S{-}{-}NH_3}\end{array}\right. .$$

—On brazilin (iv.), by A. W. Gilbody, W. H. Perkin, jun., and J. Yates. From a study of the reactions of brazilin and trimethylbrazilin, the authors conclude that brazilin probably has the constitution

$$\begin{array}{l}\mathrm{HO.C.CH:C.CO{-\!-\!-\!-}CH.CH_2.C:CH.C.OH}\\ \qquad\ \| \qquad\quad | \qquad\qquad\qquad\ | \qquad\quad | \qquad\quad \| \\ \mathrm{HC.CH:C.CH(OH){-}CH{-\!-\!-}C:CH.C.OH}\end{array} .$$

—On hæmatoxylin (v.), by W. H. Perkin, jun., and J. Yates. The study of the oxidation products of tetramethylhæmatoxylin leads to the view that hæmatoxylin has the constitution



$$\begin{array}{l}\mathrm{HO.C.C(OH):C.CO{-\!-\!-\!-}CH.CH_2.C:CH.C.OH}\\ \qquad\ \| \qquad\qquad\quad | \qquad\qquad\qquad\ | \qquad\quad | \qquad\quad \| \\ \mathrm{HC.CH{=\!=}C.CH.CH(OH).CH{-\!-\!-}C:CH.C.OH}\end{array} .$$

—Note on the function of the characteristic meta-orientating groups, by A. Lapworth.

**Anthropological Institute,** April 24.—Mr. C. H. Read, President, in the chair.—Dr. W. H. R. Rivers described a genealogical method of collecting social and vital statistics which he had used with success when in Torres Straits with the Cambridge Anthropological Expedition. Genealogies of the inhabitants of Murray Island and Mabuiag were compiled which went back for three to five generations, and included nearly all the families at present on those islands. In working out these genealogies, the only terms of relationship used were father, mother, child, husband and wife, and care was taken to limit those terms to their English sense. The chief difficulties were the prevalence of adoption in Murray Island and the custom of exchanging names in Mabuiag. The trustworthiness of the genealogies was guaranteed by the fact that nearly every detail was derived independently from several informants. These genealogies afford material for the exact study of numerous sociological problems; thus the system of kinship can be worked out very thoroughly by ascertaining the native terms which any individual applies to other members of his family, *i.e.* the subject can be investigated entirely by means of concrete examples, and abstract terms of relationship derived from European sources avoided. The genealogies also afford material for the study of totemism, marriage customs, naming customs, &c. By this method also vital statistics may be collected, both of the present and the past. The genealogies compiled in Torres Straits supply data for the study of the size of families, the proportion of the sexes, the fertility of mixed marriages, &c. The method has the further advantage of bringing out incidentally many facts in the recent history of the community, to which it gives increased definiteness and concreteness. The paper was discussed at some length by the President, Mr. Gomme and Dr. Japp.—Dr. A. C. Haddon, F.R.S., exhibited a large number of lantern slides illustrating various native industries in British New Guinea; the photographs were taken during the recent Cambridge Anthropological Expedition. The most complete series was one showing all the stages in the manufacture of pottery by Port Moresby women; other slides illustrated the manufacture of canoes at Keapara with stone implements. Photographs were shown of the process of pile-driving and the erection of buildings, as well as of fire-making, and various women's industries, such as tattooing, making string, &c.—Mr. Gowland pointed out a number of parallels from Korea to the mode of pottery-making described by Dr. Haddon.—The secretary laid before the meeting a brief account of the proceedings of the Cretan Exploration Fund, and of the discovery by Mr. A. J. Evans, at Gnossus, of a collection of clay tablets inscribed with pictographic signs.

PARIS.

**Academy of Sciences.**—M. Maurice Lévy in the chair.—The President announced to the Academy the loss by death of M. E. Grimaux, member of the Section of Chemistry.—Preparation of the β-alkyloxy-α-cyanocrotonic esters, isomers of the acetoalkylcyanacetic esters, by M. A. Haller. The true acetylalkylcyanacetic esters, $CH_3.CO.CR(CN).CO.OC_2H_5$, have been prepared by Held by acting with cyanogen chloride upon the sodium derivative $CH_3.CO.CR.Na.CO.OC_2H_5$; the isomeric ester of the enol form, $CH_3.C(OH) = C(CN).CO.OC_2H_5$, are obtained by first converting the sodium into the corresponding silver derivative, and then treating this with the alkyl iodide. The reactions of the ester so obtained are clearly those of the enolic ester, the alkyl group not being directly united to carbon. —The arable earths of the Canton of Redon from the point of view of phosphoric acid, by M. G. Lechartier. The analyses given show how it is that certain lands in the Canton have been successfully cultivated from time immemorial, without the use of phosphatic manures.—Geographical positions and magnetic observations on the eastern coast of Madagascar, by M. P. Colin. The latitude and longitude of Vatomandry and Mahanoro have been redetermined, and also the values of the magnetic elements at those places. The results show that the existing maps require correction in some respects.—Prof. Burdon-Sanderson was elected a Correspondant for the Section of Medicine and Surgery in the place of the late Sir James Paget.—Positions of fundamental polar stars determined at the Observatory of Lyons, by M. F. Gonnessiat.—Shooting stars observed at Athens during the year 1899, by M. D. Eginitis.—On the method of Neumann and the problem of Dirichlet, by M. A. Korn.—On an application of the method of successive approximations, by M. A. Davidoglou.—On the distribution of prime numbers, by M. Helge von Koch.—On gas engines, by M. L. Marchis. A reply to the criticisms of M. Witz.—An electrically driven pendulum, by M. Ch. Féry. The mechanism described is arranged so as to leave the pendulum as far as possible unconstrained.—The heat of neutralisation of hydrogen peroxide by lime, by M. de Forcrand.—Solubility of a mixture of salts having a common ion, by M. Charles Touren. The curve showing the relation between the solubility of potassium bromide in solutions of potassium bromide of different concentrations is not coincident with the corresponding curve for potassium nitrate and chloride. Hence the law proposed by Nernst, that equivalent solutions of nitrate and bromide should lower the solubility of the chloride to the same extent, is not verified. The author notes as an interesting application of the phase rule that the study of the solubility of a mixture of salts may show that they are isomorphous, when direct proof may be difficult.—The action of phenyl isocyanate and of aniline upon some γ-ketonic acids, by M. T. Klobb.—Some new compounds of antipyrine with mercury halides, by MM. J. Ville and Ch. Astre.—On acetyl-phenylacetylene and benzoyl-phenylacetylene, by MM. Ch. Moureu and R. Delange. Acetyl-phenylacetylene is quantitatively decomposed by alcoholic potash into phenylacetylene and potassium acetate; benzoyl-phenylacetylene reacts differently, acetophenone being produced.—On the stability of saccharose solutions, by M. Œchsner de Coninck.—Study of the hydrolysis of fibrous tissue, by M. A. Etard. The fibrous tissue of beef, hydrolysed with sulphuric acid, gives a polysaccharide, but practically no leucine.—On some fresh-water *Palaemonidae* of Madagascar, by M. H. Coutière.—On a new edible tuber from the Soudan, the Ousounify, by M. Maxime Cornu. The Ousounify is a tuber resembling the potato in taste, which is cultivated and sold in the Soudan. It is a labiate, and is provisionally named *Plectranthus Coppini*. It has the advantage over the potato that it can be grown in a truly tropical climate.—On the mineralogical composition of the teschenites, by M. A. Lacroix. The hornblende teschenites of Madagascar are analogous, both in structure and mineralogical composition, to the teschenites from Portugal and the Pyrenees, but they contain the nepheline intact. The teschenites from both regions were probably originally identical from the mineralogical point of view.—On the excitement of the electrical nerve of the gymnotus by its own current, by M. Mendelssohn. The electric nerve of the torpedo fish may be excited by its own current.—On the southern aurora observed during the wintering of the Belgian Antarctic expedition.—Barometric deviations produced on the parallel on successive days of the synodic revolution, by M. A. Poincaré.

## THE SCIENCE OF BACTERIOLOGY.

*The Principles of Bacteriology.* By Dr. Ferdinand Hueppe. Authorised translation from the German by Dr. E. O. Jordan. Pp. x+467. (Chicago: The Open Court Publishing Company. London: Kegan Paul, Trench, Trübner and Co., Ltd., 1899.)

IN order to fully appreciate the aim and object of the talented author of this work, it is necessary to quote a few passages from his preface. Prof. Hueppe points out that the natural history side of bacteriology has in the past been kept too much in the foreground, while the scientific side has been relegated almost exclusively to the sections dealing with protective inoculations.

> "This mode of treatment," continues the author, "no longer suffices to meet a growing and legitimate demand. In this book I wish to present an attempt at a critical and comprehensive exposition of bacteriology, basing it clearly and solidly upon scientific conceptions. I make this essay in order that our knowledge of the causes of putrefaction, fermentation and disease, together with the methods of the prevention and cure of infection, may develop in a way free from all ontology. It is sometimes of use to restate things which are axiomatic. The 'entities' or 'essences,' which, even in the age which has discovered the law of the conservation of energy and the evolution of living things by means of the struggle for existence, still haunt the mind of the physician who remains sunk in the ontological contemplation of diseased cells and disease-producing bacteria, are a mere remnant of priest medicine, and can have no place in any scientific conception of biology, pathology or hygiene."

The first chapter (pp. 1-49) in the book deals with "The structure of bacteria." No greater authority on this subject than the author could be named; yet, in view of the highly important questions discussed in Chapters iv.-vii., one is led to doubt whether this portion of the book is not a little out of keeping with the scope of the work as a whole.

The "Vital phenomena of bacteria" are discussed in Chapter ii. (pp. 50-138). Although the subject is most ably dealt with, most of the information given may be found in nearly every text-book of bacteriology. Considering the important character of the rest of the book, this chapter seems unduly long.

In Chapter iii. (pp. 146-219) a brief description of the most important pathogenic bacteria is given. Here the author paves the way for the discussion of the important questions which crop up later in the book. It is curious to note that Prof. Hueppe, although considering that the evidence is most in favour of *B. typhosus* and *B. coli communis* being two distinct species, is by no means dogmatic on the point. Thus he says, on p. 193:—

> "There are, in fact, at present two opposing views. The one, which to me seems to be the better founded, is that the bacteria of typhoid fever and *B. coli communis* are two distinct species. The other view is that the common intestinal saphrophyte, *B. coli communis*, is an æco-parasite which, under special conditions, may become able to invade the body and penetrate into the living organism, where it undergoes transformation into the typhoid bacterium."

At the end of this chapter Mr. Jordan contributes a brief *résumé* of Sanarelli's recent papers upon yellow fever. The summary is concisely and well written, and enables one to comprehend without difficulty the extent and value of Sanarelli's researches. The remaining chapters are full of originality, and invite most careful reading and serious attention.

In Chapter iv. (pp. 221-274) the "Cause of infectious disease" is discussed with conspicuous ability. The author endeavours to show what is false and what is scientifically tenable in the different conceptions of the true and sufficient cause of epidemic disease upheld by such authorities as Koch, Virchow and Pettenkoffer.

> "Virchow finds an internal cause in the diseased cells; his opponents see an external cause in the germs that bring about the disease; and Pettenkoffer sees a cause in those external conditions which play no particular *rôle* either in the eyes of Virchow or in those of Virchow's chief opponents."

If the writer does not altogether succeed in his object, he at all events widens our horizon of thought to an extent which is quite remarkable. It will not be out of place to quote a single paragraph—

> "If the facts are considered in a scientific spirit rigorously and without prepossession, it is seen that the sum of the qualities of a disease germ is only apparently the 'essence' of an infectious disease, that, in reality, here as elsewhere, a true internal cause is to be found, inherent in the internal organisation of man. Just as in all natural processes, without exception, so here, the disease germs act as liberating impulses, and are able to set free only what in the form of a predisposition toward disease is in some way prefigured both in nature and amount in the human body."

In Chapter v. (pp. 275-294) the author asks the question—"Can disease be cured by combating the cause?"

In speaking of Hahnemann's doctrine of the value of small doses, the author passes the following criticism on homœopathy:—

> "Even the childish extravagance which found vent in homœopathy could not impair the sound kernel of truth which the doctrine contained."

Although Prof. Hueppe's whole book ought to be read by all those physicians who are modest enough (happily, the great majority) to believe that there is something still to be learnt in the theory and practice of medicine, this chapter is especially full of suggestions and original observations, which the thoughtful practitioner would do well to study.

Chapter vi. (pp. 295-397) treats of "Immunity, protective inoculation, and curative inoculation." It is, perhaps, the most important chapter in the book, and it is impossible in the limits of this notice to do the author full justice. It may, however, be said that it deals with a most difficult and complex subject in a way that is to be highly commended. That it is "stiff" reading cannot be denied, but that is not the fault of the writer, but of the subject. A careful perusal of this portion of the book will well repay the physician as well as the bacteriologist.

The "Prevention of infectious diseases by combating the cause of the disease" is the text of Chapter vii. (pp. 398-439). Here we are not altogether in sympathy with the writer, although his views are clearly and forcibly expressed, and are in the main in touch with the teachings of modern sanitarians.

It is to be regretted that in this chapter the author allows his personal antagonism to Koch's doctrine of disinfection to weaken his arguments and conclusions. That the followers of Koch sometimes carried disinfection too far does not detract from the value of Koch's original observations.

Prof. Hueppe lays peculiar stress on the importance of making infectious disease impossible by removing the predisposition to disease, but he scoffs at the idea of combating disease by warring directly with the germs of disease. Although there is a great deal to be learnt from this chapter, it seems a pity that so able a writer should have marred his own work by a captious criticism of Koch's able investigations.

The last chapter (pp. 440–455) deals with the "History of Bacteriology." Ably written though it is, it, like the first chapter, appears to be foreign to the general scope of the book.

In summary of the book as a whole, it may be said that it affords more ground for serious thought and reflection than perhaps any of the works on bacteriology hitherto published. The original and able manner in which the author attacks biological problems of great difficulty and complexity deserves all praise, and we can cordially recommend the book, not only to bacteriologists pure and simple, but also to those physicians who recognise the limitations of medical science.

Much praise is due to the translator. Mr. Jordan's worth as a bacteriologist is well known and fully appreciated. By giving us this translation of Hueppe's work he has added to his reputation. A. C. HOUSTON.

---

## *SUNSHINE AND WINE-GROWING.*

*Vinification dans les Pays chauds—Algérie et Tunisie.* Par J. Dugast. Pp. 281; 58 figures. (Paris: Carré et C. Naud, 1900.)

ACCORDING to the preface, valuable scientific and technical works on the production of wine in temperate climates have been published both in France and elsewhere; but so far the special problems which are encountered by wine-growers in the warm climates of such countries as Algeria and Tunis have remained unnoticed. The present work is intended by the author to fill this blank. But although it has been written specially with a view to describe the difficulties peculiar to wine-making in a warm climate and the means of overcoming them, the author has done more than this, for he has found it advisable, in order to make his purpose quite clear, to embody his special subject in a general scientific and technical description of wine-making. As he has had very considerable practical and scientific experience in his subject, the result is a work well worth the attention of all interested in the making of wine.

The most common difficulty of the Algerian wine-grower, and one which is very rare in the more temperate climate of France, is due to the must, or grape juice, very frequently containing too little acid and too much sugar as a result of very active plant assimilation induced by excessive solar radiation. Deficiency of acid is apt not only to affect injuriously the flavour of the resulting wine, but also to induce unsoundness; the latter effect being caused by the low acidity of the wine favouring the growth of injurious bacteria, which the higher acidity of a normal wine tends to inhibit, owing to the well-known fact that an acid medium is unfavourable to the development of most ferment bacteria.

The means employed to remove the difficulty of want of acidity, which are described by the author, let us into secrets of wine-making which some may perhaps be inclined to think border on sophistication. Plastering is one which is undoubtedly objectionable. It consists in adding calcium sulphate to the crushed grapes, which results in the formation, from the cream of tartar present in the must, of sulphate of potash. But this method, though evidently made use of by many wine-growers, is condemned by the author, and also discouraged by the French law, which limits the amount of sulphate of potash to two grammes per litre.

Other methods for increasing the acidity of the must are: crushing a certain quantity of unripe sour grapes with the ripe ones; the addition of tartaric acid to the must previous to fermentation; and sprinkling the grapes in the wine-press with, what the author styles, di-calcic phosphate. The latter treatment is said to result in the formation of acid phosphate of potash, a salt considered by the author to be less objectionable than sulphate of potash.

Excess sugar in the must acts detrimentally by throwing too much work on the yeast, which is itself apt to be crippled in the hot climate of Algeria by an exceedingly high fermentation temperature. Mention is made of the fermentation temperature at times rising to upwards of 115° F.—which in itself is sufficient to arrest the fermentation functions of most yeasts.

About 20 per cent. of sugar is considered the most favourable amount for a wine must to contain, and if the saccharometer shows that it exceeds this amount, the best remedy appears to be the simple and inexpensive use of the pump.

An interesting point, about which much has been said of late years, is raised by the author when he deals with the question of the use of pure selected yeasts in the fermentation of wine. It has been advanced by certain upholders of this system that the characteristic flavour or bouquet of most well-known wines is produced in the main by the variety or species of yeast natural to the grapes of the district, and that, if pure cultures of such yeasts are made use of in the fermentation of foreign musts, the flavour of the resulting wines assume the character of the wines of the district from which the yeasts were obtained.

The idea is evidently one of the greatest importance to the wine industry, as it holds out hopes of improving the wine of poor districts into something like, let us say, first quality clarets or Burgundies. The author of this book states that selected yeasts have been much used by the wine-growers of Algeria, and he claims to have had ample opportunities for studying the results. The conclusion he arrives at is that the yeast from a noted growth of wine, when added to an ordinary must, is quite powerless to confer on it the special qualities of the wine from which it comes; and he further concludes that yeast has little, if any, influence on the bouquet of wine. The true character of a wine, he maintains, is due to numerous factors, among which the variety of grape and the character of the soil and climate preponderate; if the yeast does produce any flavour, it is indistinguishable among these.

If, however, the author passes adverse judgment on selected yeasts regarding their power of conferring flavour, he does not do so with regard to their use for setting up a rapid and healthy fermentation in wine must. For this purpose he advocates their use warmly, but insists on the employment of a selected indigenous yeast as more calculated to be in harmony with the environment than if it was derived from a foreign source.

The valuable results which have accrued from Emil C. Hansen's remarkable studies on yeast have already led to so many successful results in technical practice, that we still feel inclined to suspend judgment regarding the non-efficiency of wine yeast in the matter of flavour until M. Dugast's interesting observations are confirmed in other quarters.

In conclusion, we call special attention to this book as likely to be useful to our Colonial wine-growers of Australia and the Cape; the climate of these countries is somewhat similar to that of Algeria, and no doubt some of the special difficulties discussed in this book are also met with in these countries. A. J. B.

---

## THE FAUNA OF THE SHETLANDS.

*A Vertebrate Fauna of the Shetland Islands.* By A. H. Evans and T. E. Buckley. Pp. xxix + 248. (Edinburgh: D. Douglas, 1899.)

ALTHOUGH it would be too high a meed of praise to say that the authors have done for the Shetlands what Gilbert White did for Selborne (the systematic treatment of the fauna not being favourable to colloquial writing), there is no doubt that they have succeeded in producing a very interesting volume, and one which should be indispensable to every visitor to the most northern group of the British Islands, whether or no he be specially interested in birds. For in place of restricting themselves to a detailed account of the various members of their vertebrate fauna, Messrs. Evans and Buckley have furnished a very interesting description of the more striking physical features of these islands, together with numerous notes on the people and their mode of life. But perhaps the most generally attractive feature of the work will be the exquisite views of Shetland scenery with which it is adorned; these illustrations reflecting the highest credit alike on the photographer and on the artist responsible for their reproduction in the present form. In introducing these scenic pictures, in place of figures of the birds recorded as members of the fauna, the authors have undoubtedly exercised a wise discretion. In only one instance have they made a natural history object the chief feature of an illustration; the one exception being the beautiful plate of the nest and young of the great skua—a bird of all-absorbing interest to the naturalist in the Shetlands.

And here it is proper to mention that the volume before us forms a part of the vertebrate fauna of Scotland, of which several volumes by Messrs. Harvie-Brown and Buckley have already appeared. It seems that Mr. Evans, who has an extensive personal acquaintance with the Shetlands, had an idea of writing an independent work on its animals. The securing his services as a contributor to the larger undertaking will commend itself to all.

After devoting fifty-four pages to a well-written description of the physical features of the country, the authors proceed to their proper subject—the detailed account of the vertebrates, which includes both the terrestrial and the marine forms. In the classification of the birds they follow in the main the scheme of Mr. H. Saunders, and though they suggest that some amendments might perhaps have been made had it not been for the sake of uniformity with the "Fauna of Orkney," yet we are glad to know from his volume in the Cambridge "Natural History" that Mr. Evans, at least, is no friend to the plan of unnecessarily multiplying the genera of British birds, nor to the "*Scomber scomber*" principle.

In the classification of mammals, especially when we note the statement that Mr. Eagle Clarke has *carefully* revised the proofs, it is somewhat surprising to find the narwhal included among the *Physeteridae*. Neither do we see the necessity of regarding the rorquals as the representatives of a family by themselves. But, altogether apart from such trivial details, we must take exception to the practice of including introduced species among mammalian faunas. In the present instance the authors note five species of rodents as belonging to the Shetland fauna, whereas only one of these—*Mus sylvaticus*—is really indigenous. The trouble such methods cause to those who have occasion to write on the geographical distribution of animals is best known to themselves. If introduced forms are mentioned at all, their foreign origin ought to be indicated in such a manner that it will catch the eye of the reader at the first glance. In the case of birds, such as the ruff, which but rarely visit the islands, some conspicuous notification of the fact would likewise be advantageous, although we are ready to acknowledge that the line between regular visitors and accidental stragglers is very hard to draw.

The above mention of *Mus sylvaticus*—the long-tailed field-mouse—reminds us that one of the most important objects of histories of island faunas is to point out whether the indigenous animals are in any way distinguishable from those inhabiting the nearest mainland. In the case of birds of strong flight such differences are not likely to occur, but they should be looked for in birds that never leave their island home, and in the indigenous mammals. On the special characters of the Shetland field-mouse the authors are silent, which in view of Mr. Barrett-Hamilton's recent recognition of a peculiar representative of this type in St. Kilda is distinctly to be regretted. In the case of the common wren, which has likewise a peculiar local race in St. Kilda, the authors state that the Shetland form differs to a certain extent from the one found on the Scottish mainland, although not, in their opinion, sufficiently so as to be entitled to be regarded as representing a distinct race. If this be so, and the field-mouse be indistinguishable from the mainland form, it suggests that the Shetlands have been separated from the mainland at a later date than have the Hebrides;—but this is just one of the cases where we should have liked a well-considered opinion from the authors!

In an area like the Shetlands the great interest, from a faunistic point of view, centres on the birds; and among these the great skua holds the foremost place, since its only British breeding-stations are on these islands. So much has been of late years written on this subject, both in newspapers and in ornithological journals, that it is one with which the public are tolerably well acquainted. Nevertheless, the account given by the authors of the almost complete extermination of this fine species, and its subsequent rehabilitation by the efforts of various members of the Edmonston family and Mr. Scott, of Melby, will be read with interest, and forms a concise summary of the whole affair. We should, however, like to know more with regard to the meaning of the statement that "protection for the skuas implies some measure of protection also for the gulls; but unless the latter greatly increase, the former cannot be expected to do so."

Some interest also attaches to the specimen of the collared pratincole killed by Bullock in 1812, as being the only example of the species hitherto shot in North Britain. In the fourth edition of "Yarrell" the skin is stated to be in the British Museum, but the investigations of the authors fail to confirm this statement.

Greater attention is, however, merited by the account of the nesting of the storm petrel, which sometimes lays its eggs among large stones on the shore, and in other cases selects deserted rabbit-burrows for its home. The crofters, knowing the value set on the eggs of this bird by collectors, and being likewise extremely partial to young petrels as a *bonne bouche*, are extremely reluctant to indicate the rabbit-holes in which the birds nest to strangers.

To many it will come as a surprise to learn that ravens are still common in the islands; so numerous, indeed, as in certain districts to prove very destructive to the poultry and stock, on which account war is waged against them by the crofters. In contrast to the abundance of these birds is the scarcity of rooks, which are, indeed, little more than casual visitors to the islands.

The weakest point about the book is undoubtedly, as the authors themselves are fain to confess, the section on fishes, the classification followed being altogether obsolete and discredited. R. L.

## PHYSICAL CHEMISTRY.

*Introduction to Physical Chemistry*. By James Walker, D.Sc., Ph.D. Pp. x + 332. (London: Macmillan and Co., Ltd.)

IT is now nearly ten years since Prof. Walker placed English students under obligation by his admirable translation of Ostwald's "Outlines of General Chemistry." Since that time "little Ostwald" has been the source from which most students have taken their first draught of information about physical chemistry in its modern form. The phrases and paraphrases of the book, the diagrams, the perpetual motions "which are impossible" have become almost painfully familiar to the examiner. The present writer is one of those who believe that Ostwald's book has been of the highest service to chemistry. At the same time, it must be admitted that it is one to be used with care. There is an illusory appearance of simplicity about it, and if care be not taken the use of the book is eminently calculated to lead to a learned smattering. It is, in fact, a book which forms the summary of a course of instruction, and for beginners it must be supplemented by an extended commentary by an experienced teacher.

These observations arise inevitably in connection with Prof. Walker's new book, which, in size, appearance and typography, as well as in its topics, bears so striking a resemblance to Ostwald's "Outlines." The first question that the reader will ask is—Where lies the difference between the two books? This question is soon answered as one reads; Prof. Walker's book is more limited in range and incomparably simpler. To quote the author's words, it "makes no pretension to give a complete or even systematic survey of physical chemistry"; the aim is to give a full discussion of some of the chief principles of modern physical chemistry, and to show their application to ordinary laboratory chemistry.

Dr. Walker has achieved his purpose in a most satisfactory manner, and has produced a book which will be a real boon to students of physical chemistry. He writes with the knowledge of a specialist and the experience of a teacher, and it is very striking to any one who knows the difficulties of students to see how perfectly Dr. Walker appreciates them. Not less striking are the expository power and resourcefulness with which the difficulties are handled. Whilst the whole book is clear, readable, and abreast of the times, some chapters deserve special attention. The one on chemical equations is amongst these. It gives a rational account of the art of constructing chemical equations by dissection and summation, a subject which has been strangely neglected by text-book writers. The chapter on fusion and solidification is made very clear by a thorough discussion of the mutual relations of salt, ice and water. The wide generalisation, or group of generalisations known as the Phase Rule, is expounded within reasonable limits. Hitherto there has been nothing concise on this subject in the English language. The chapters relating to the modern theories of solution are, it need scarcely be said, written with fulness of knowledge and in the spirit of a true believer in the doctrine of electrolytic dissociation. Chemical dynamics is treated succinctly, and admirably illustrated by examples. There is a distinct gain here in departing from the strict historical development of the subject, which is apt to confuse beginners by the series of fresh starts which it involves. The concluding chapter on thermodynamical proofs is made as clear as it well could be. At the end of each chapter references are given to original articles which have appeared in English journals and to English books. The list of these is quite gratifying, but the wisdom of confining the references to English publications seems questionable. The extraordinary backwardness of students in acquiring a reading knowledge of German is condoned by such a restriction; and, besides this, it would have been a service to many students who have some knowledge of the language if Dr. Walker had helped them to select the really important pioneering papers from the vast periodical literature that has arisen in Germany during the past ten years.

In concluding this notice, one is naturally led to reflect upon the attitude which appears to be still maintained by a number of English chemists in regard to the modern theories of solution. There can be no doubt that a student reading Dr. Walker's book will become imbued with these theories, and will acquire convictions that will be difficult to eradicate. If these theories are wrong, if they are even strongly suspect, the responsibility of the teacher becomes serious It is true Dr. Walker gives here and there some indications of the objections which have been urged against them, but there is no explicit statement of the opposition case. The question arises whether an opposition case can be explicitly stated. The theory of ionic dissociation has been applied to explain and co-ordinate a very large number of chemical facts, and has thrown light on matters that were previously dark. The contention of the objectors appears to be mainly that this light is illusory. The present writer is far from claiming judicial functions in the matter; but he ventures to think that the opposition to the dissociation theory would be more respected, both here and on the Continent, if it were of a more positive character, and if a more tangible alternative theory could be presented which should prove itself not less comprehensive and practically productive than the one which is assailed. The history of science shows plainly enough that a comprehensive theory with some weak points will hold its ground until a not less comprehensive theory with fewer weak points makes its appearance. It is probably on this ground that Prof. Walker takes his stand in freely imparting the doctrine of electrolytic dissociation to elementary students of physical chemistry. ARTHUR SMITHELLS.

---

## *OUR BOOK SHELF.*

*Catalogue of the Lepidoptera Phalaenae in the British Museum.* Vol. ii. Catalogue of the Arctiadæ (Nolinæ, Lithosianæ) in the collection of the British Museum. By Sir George F. Hampson, Bart. Pp. xx + 589, and plates xviii–xxxv. (London: Printed by order of the Trustees, 1900.)

THE first volume of this series, containing the Syntomidæ, was published in 1898, and we have now to welcome the appearance of the second, comprising two groups, which the author treats as sub-families of the Arctiadæ; the typical Arctianæ being reserved for the third volume. 1193 species are described in the second volume, all of which, except 162, belong to the Lithosianæ, the Nolinæ being a comparatively small sub-family.

The enormous extent of the insect-world is but little realised, even by naturalists, unless they are entomologists; but, considering the progress already made, we are probably well within the mark in saying that it may well take fifty volumes, and the whole of the new century, to complete the Catalogue before us; and yet the moths are only a portion of one of the seven principal orders of insects, and one which is probably far surpassed in number of species by at least three other orders.

The descriptions of the species are necessarily brief, but are arranged on a uniform plan which admits of easy comparison; and their determination is further facilitated by comprehensive tables of genera and species, and by the large proportion which have been figured, either in the crowded coloured plates, or in text-illustrations. We are glad to see that space has been found for notices of larvæ, when known. Space has also been devoted to phylogeny; but it is, perhaps, an open question whether it is worth while to deal with this subject in a descriptive work at all. At best, it can only express the momentary and necessarily fluctuating opinions of an individual author on the affinities of genera and species from the very imperfect materials at present available; for until the earlier stages of a considerable number of forms have been carefully studied and tabulated for comparison, it is impossible for us to judge of them completely or accurately. We would therefore prefer to treat this branch of the subject tentatively, in ephemeral publications, rather than to introduce a necessarily fluctuating factor, of merely temporary value at best, into a standard work of reference, of such great and permanent value to all lepidopterists as the present. We must also object to the author's tendency to dogmatise on the subject, especially as our knowledge of fossil insects is at present practically nil, and of the early stages of the great majority no better. Such a phrase as [the Arctiadæ form] "a family of moths derived from the Noctuidæ," seems to us quite out of place in a scientific book at the present state of our knowledge; though a formula which we find a little further on is less objectionable; "the *Nolinae* probably arose from a very early Arctian form which had affinities in the *Noctuidae* to *Hypenae* and *Sarrothripae*."

But these are details of individual taste or judgment; while there cannot be two opinions respecting the value and importance of the work. W. F. K.

*Giordano Bruno, zur erinnerung an den 17 Februar,* 1600. Von Alois Riehl. Zweite neu bearbeitete Auflage. Pp. iv + 56. (Leipzig: Engelmann, 1900.)

EARLY in 1600 Giordano Bruno went to the stake in the cause of free speech and thought. The ashes of martyrdom have ere now kept evergreen even reputations and names that were otherwise of little worth. But Bruno's life and work are alike memorable. Few, however, of those to whom the romantic wander-years and heroic death appeal, have leisure and training to grapple with the technical Latin and hard Italian of the versatile and stormy Nolan. The tercentenary, therefore, of Bruno's tragedy can have no memorial more fitting than Prof. Alois Riehl's "Giordano Bruno." Would that it were in English! Dating originally 1889, Prof. Riehl's brochure has undergone revision thorough and throughout. It puts Bruno in his right setting of time and place. It resumes, with brevity and lucidity quite noteworthy, the principles for which Bruno gave his life. Bruno originated neither Copernican physics nor pantheist metaphysics. His debt to one close forerunner at least is not small. Yet in taking the new astronomy as a scientific basis, and only therefrom passing to such metaphysical conceptions as infinity and unity, while reaching out ultimately to a monistic principle, it is Bruno and not his precursors, physicist and revived neoplatonist, that may claim to father modern naturalism. Prof. Riehl characterises the system as "theocentric," since nature is, for Bruno, *deus in rebus*. Bruno is said to have met the process which resulted in his condemnation by equivocating between what he accepted *secundum fidem* and what he affirmed *secundum rationem*. At any rate, whatever human weakness he may have shown, he lost no opportunity of reaffirming his principles. He recanted nothing. He could have saved himself would he but have prostituted his pen to apologetics on behalf of the reigning orthodoxy. He chose not *propter vitam vivendi perdere causas*. And he died a knight-errant of the free spirit. H. W. B.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Escape of Gases from Atmospheres.

I ASK for space to reply to Mr. Cook's letter in last week's NATURE.

There are two ways in which the rate at which gases escape from atmospheres may conceivably be investigated, viz. the *a priori* method, which seeks to determine from the kinetic theory of gas what proportion of molecules attain the requisite speed; and the *a posteriori* method, which seeks to ascertain from the observed effects of escape where and on what scale it has actually taken place.

I tried the *a priori* method more than thirty years ago, but had to abandon it, having satisfied myself that *in the present state of our knowledge it cannot be made to furnish a valid investigation.* I came to this conclusion upon grounds which are fully stated in a paper of which the first part will appear in the May number of the *Astrophysical Journal*, and the second and more important part probably in the June number. I then turned to the *a posteriori* method, and endeavoured to develop it in the memoir which Mr. Cook has criticised (see *Scientific Transactions* of the Royal Dublin Society, vol. vi. (1897), p. 305, or *Astrophysical Journal* for January 1898, p. 25).

Both methods, if correctly applied, should lead to the same results: but the *a priori* method, as handled by Mr. Cook and Prof. Bryan, furnishes a different rate of escape from the *a posteriori* method. In such cases there must be a mistake or mistakes somewhere, and in the above-mentioned paper sent to the *Astrophysical Journal* I have endeavoured to trace out where the mistakes are.

The principal errors seem to be three.

The number of molecular speeds which lie between $v$ and $v+dv$

$$= N(\pi+\delta)dv$$

where N is the number of molecular speeds whose distribution is under consideration, $\pi$ is the probability function (in this case Maxwell's law), and $\delta$ may be called the deviation function, as it furnishes the difference which exists between the actual number and that computed by Maxwell's law. In all cases of probability laws the deviation fuction $\delta$ is large when N is small; but when the events whose distribution is sought are independent of one another and have causes all of one kind, then $\delta$ becomes inconspicuous when N is sufficiently large, and the distribution law may *in such cases* be reduced to $N\pi dv$ without sensible error. This reduction, however, is not always legitimate when, as in gases, the events are so associated with one another and with other agencies that cumulative effects can arise. Then $\delta$ may become larger than $\pi$ in reference to those values of $v$ which make $\pi$ small. The first omission seems to be the omission to take this into account.

Another omission is the omission to take the size of the element of volume $dxdydz$ into account. This, as experiment shows, may at the bottom of the earth's atmosphere be as small as the cube of one-tenth of a millimetre. But in the regions from which the escape of gas is possible, it has a volume of many cubic miles. This circumstance, which largely increases the opportunity which molecules have of escaping from that situation, has not been taken into account.

But perhaps the most serious error is overlooking the fact that Maxwell's law holds good only of a portion of isotropic gas surrounded by similar gas. That the gas shall be isotropic is one of the data employed by Maxwell in his proof of the law. Another law (which may be, and in fact is, very different from Maxwell's) is the law of distribution of the molecular speeds in a portion of gas as anisotropic as that of the regions from which the actual escape takes effect. The deductions from Maxwell's law may be correctly derived, but the premiss being wrong the conclusion has no significance.

It would be very satisfactory if we had two ways—the *a priori* method as well as the *a posteriori*—of investigating the problem; but with our present limited knowledge of molecular physics, this does not seem to be within our reach.

Mr. Cook at the end of his letter supposes that "the discovery by Ramsay of helium as a constituent of our atmosphere only tends to confirm the results of my (Mr. Cook's) calculations of the impossibility of its escape." This is so far from being the case that the quantitative determinations made in Prof. Ramsay's laboratory are now sufficiently advanced to lead with much increased emphasis to the opposite conclusion. This appears from the following data, which have been generously placed at my disposal by my friend, Prof. Ramsay:—

(1) The proportion by volume of argon in dry atmospheric air is about 1 per cent. of the whole, the volume of neon (to which the present note will not further refer) may be taken as about a thousandth part of the volume of argon, and the volume of helium as about 1/10 to 1/20 of the volume of neon. Accordingly, the volume of helium in dry air is something like from 1/10,000 to 1/20,000 of the volume of argon, or from 1/1,000,000 to 1/2,000,000 of the whole volume of the air.

(2) Both argon and helium are supplied to the atmosphere by hot springs; argon generally by all hot springs which contain atmospheric gases, and helium by some of them.

(3) The argon in such springs, like the oxygen and nitrogen, may be simply gas which had previously been removed from the atmosphere by water. A litre of water under ordinary conditions will absorb about 45 c.c. of the oxygen of the air in contact with it; about 15 c.c. of its nitrogen; about 40 c.c. of its argon; and about 14 c.c. of its helium.[1]

Hence in rain we should expect to find the following proportions preserved:—

$$\frac{20\cdot9}{100} \times 4\cdot5 \text{ of } O_2;$$

$$\frac{78\cdot1}{100} \times 1\cdot5 \text{ of } N_2;$$

$$\frac{1}{100} \times 4 \text{ of A; and}$$

$$\left.\begin{array}{l} \text{from } \dfrac{1}{1,000,000} \times 1\cdot4 \\ \text{to } \dfrac{1}{2,000,000} \times 1\cdot4 \end{array}\right\} \text{of He.}$$

So far as oxygen, nitrogen and argon are concerned, these proportions are sufficiently nearly those in which the gases are present in the springs referred to. But in those springs in which helium also has been detected, it seems to be present in quantities about 1/10 of the argon—that is, in a quantity which is nearly from 3000 to 6000 more than we can attribute to its having been derived from the atmosphere.

(4) This great excess of helium in some springs has doubtless a mineral origin, some minerals, chiefly uranium compounds, containing much helium which they give up when heated. On the other hand, there does not appear to be any comparable mineral source of argon.

(5) Hence, on the whole, the argon which is being supplied to the atmosphere by hot springs seems to be argon which had previously been withdrawn from the atmosphere and which is being restored to it. Whereas, in contrast to this, there seems to be a continuous transfer of additional helium from the solid earth to the atmosphere always going on.

Thus the facts seem to warrant our inferring:—

(*a*) That the excessively small quantity of helium in the atmosphere is helium on its way outwards.

(*b*) That it would have become a much larger constituent of the atmosphere, by reason of the influx from below, if there had been no simultaneous outflow from above.

(*c*) That the rate of this outflow is presumably equal to the rate of supply; and therefore such as would suffice in a few thousand, or at least in a few million, years to drain away the small stock of helium in the earth's atmosphere, if the source of supply from below could be cut off.[2]

---

[1] See the determinations made by Herr Estreicher in Prof. Ramsay's laboratory, as recorded in the *Zeitschrift für physikalische Chemie*, vol. xxxi. (1899), p. 184.

[2] If the proportion of helium in the atmosphere is assumed to be something between 1/1,000,000 and 1/2,000,000 of the whole atmosphere (which rather tends to be an over-estimate, since it does not take into account the increased diminution of the density of the helium as it ascends, which is a consequence of its escape from the top of the atmosphere), then the helium in the whole of the earth's atmosphere would, if reduced to standard temperature and pressure, occupy a volume somewhere between a cube of ten miles, and half that space. Now, so far as can be judged from the imperfect observations as yet made on the rate at which helium is being filtered into the atmosphere, it would appear that the present rate of supply is such as would yield this quantity of helium in something like one or two thousand years, and perhaps in a less time.

It thus appears that the recent more exact determinations have raised what was probable when I wrote my memoir into being now almost certain, by showing with greatly increased clearness—

(1) That argon is unable to escape from the earth.

(2) That helium is slowly escaping, and presumably was in a position to escape more freely in the distant past.

It is interesting to observe that another moot question in astronomy seems to be resolved by Prof. Ramsay's work. It is known that the dynamical relation of the vapour of water to Mars is nearly the same as that of helium to the earth. We are accordingly now justified in presuming with greater confidence that water cannot remain upon Mars, that accordingly the polar snows of that planet are probably carbon dioxide, and that some of the other appearances which have been observed are due to the shifting of low-lying fogs of this vapour as they travel alternately towards the two poles.

G. JOHNSTONE STONEY.

8, Upper Hornsey Rise, N., May 20.

### "Plotosus canius" and the "Snake-stone."

POSSIBLY the following facts may possess interest for some of your readers:—

A good many years ago, when sea-bathing in the Old Straits of Singapore (*i.e.* those separating the island from the Malay Peninsula), I put my foot in a slight muddy hollow in the sandy sea-bed; the moment I did so, I received an agonising stab near the ankle (from some red-hot poisoned blade, it seemed) which drove me in hot haste ashore, where a Malay constable, on hearing what had happened, and on examining the wound, pronounced my assailant to be the "ikan sĕmbílang" (sĕmbílang fish), *Plotosus canius*, one of the siluroids, I am informed by Mr. Boulenger of the British Museum. The fish is armed with three powerful spines on the head, one projecting perpendicularly from the top, and one projecting horizontally from each side.

The Malay lost no time in running to the barracks near by, whence he shortly returned with a little round charcoal-like stone about the size of a small marble. This he pressed on to the wound, to which it adhered, and remained there by itself, without any continuation of pressure, for a minute or more. Then it fell off, and black blood began to flow, which, after a little, was succeeded by blood of normal colour. The pain, which had been excessively acute, began to diminish soon after this, and in an hour had practically disappeared. The wound gave me no further trouble, but a fortnight afterwards I noticed a hole about the size of a pea where the wound had been.

Another gentleman, who, curiously enough, had suffered in the same way in another part of Singapore the same day, was not so fortunate in his cure, being completely laid up for six weeks.

The black stone applied by the Malay to the wound came, he alleged, from the head of a snake, and claimed, therefore, to be a bezoar stone. It was, no doubt, a snake-stone, probably made of charred bone, and therefore porous in character, which would account for the adhesive and absorptive powers it displayed in my case.

In his "Thanatophidia of India," Sir J. Fayrer (quoted by Yule in "Hobson-Jobson") expresses entire disbelief in the efficacy of these stones as remedies "in the case of the *real bite* of a *deadly* snake," owing to the extreme rapidity with which, in such a case, the venom pervades the system.

However this may be, the late Prof. Faraday, after examination of one of these stones, supplied by Sir Emerson Tennent (quoted by Yule), credits it with certain absorbent powers, and it would seem a pity that the undoubted value of such stones, at all events in minor cases, where they may save a great deal of suffering, should be discredited.

Another remedy, considered of some value by Malays for the stab of *Plotosus canius* is the sap of *Henslowia Lobbiana*, which grows freely on the coasts of the Malay Peninsula.

Among other marine offenders of this class dreaded by Malays are several varieties of the skate or sting-ray, "pari" as they are generically called, and some of the "lĕpu," of which the only dangerous one, I have Mr. Boulenger's authority for saying, is the "lĕpu" proper, viz. *Synancia horrida*. When the skate reaches a large size, he will drag a fisherman's canoe a long way.

Among the Medusæ, one much dreaded is known as "ampai," from its long fringes. The effects, unless a remedy can speedily be found, are painful and trying to a degree, seeming to penetrate the whole frame, as it were, electrically, at once specially affecting the seat of any ailment, and even the teeth and the hair. I have never suffered from it myself, but am enabled to speak to these points from two cases which came under my personal observation. A valuable remedy for this sting, if applied soon, is the juice of the young fruit of the papaw (*Carica papaya*).

A further illustration of the value of some native remedies is supplied by a case which occurred some years ago at Malacca, during my residence there, though I cannot state what the remedies employed were.

A young gentlemen in the office of the Telegraph Company went out to bathe in the sea one night from the end of the pier (in any case rather a rash proceeding, if only for the occasional presence of crocodiles !), when he found himself in the embrace of some creature with long tentacles, from which, after desperate struggles, he eventually succeeded in freeing his legs and his arms, and in regaining the pier. The Colonial surgeon could do nothing for him, and he was in such tortures that for a time he seemed to have lost his mental balance, but nine or ten days after the occurrence a native practitioner, being called in, cured him completely.

D. HERVEY.

The Elms, Aldeburgh, May.

### Microphotography, Isophotography, Megaphotography.

I HAVE read with much interest your article on microphotography (p. 4) at its best. Possibly some of your photographer readers may be glad to know that microphotography of sorts is within the reach of all who possess a microscope with suitable substage-condenser and a camera. The results may not compete with the best, but they are very useful. I find that any transparent object which can be conveniently seen in the microscope can be reproduced in the camera. If the fine adjustment is good enough for ordinary work, it is good enough for photographic work.

One of my earliest attempts was to photograph fluid inclusions in quartzes with ordinary sunlight, and rock-sections polarised. The only difficulty was that the sun would not keep still, and without a heliostat the work was most troublesome, not to say aggravating. In one case, a mere movement of the condenser-diaphragm made the bubble in the inclusion fly backwards and forwards. A negative was taken in each position, and a lantern slide taken of each negative. With a little device in the double lantern the motion of bubbles in inclusions can be shown on a nine-foot screen. These negatives were taken with a 1/16th immersion, the camera being extended with a brown paper tube, and the extra apparatus did not cost one shilling.

Up to a ½-inch objective, ordinary gas, with isochromatic plates, does very useful work. The only difficulty to surmount is to handle the focusing apparatus, and see the focusing screen at the same time. A hand mirror solves the problem. But a fine adjustment is really scarcely necessary, as it is easy to focus with the camera as in ordinary photography.

It is often desirable to photograph objects their exact size. Before the Kent's Cavern Collection was divided, I photographed the choicest examples for the Torquay Natural History Society. The implements were fixed with beeswax on a piece of plate-glass, which could be placed in any position and backed by any desired background. I sent a couple of prints to the International Amateur Photographic Exhibition at Vienna, and the jury, much to my surprise, awarded them a diploma. The extra apparatus certainly did not cost 10*s*., and the negatives were taken in the lecture-room of the Natural History Society under some disadvantages.

Of megaphotography I have but a single experience. While observing the transit of Venus, I thought I would try a photograph. I drilled a hole in the telescope cap for diaphragm; took off the eye-piece and stuffed the telescope into a common camera, with a red cloth to make it light-tight; exposed six negatives with hand exposure on instantaneous plates. Result: four passable negatives and one good one. This quite unlooked-for success was due to some back volumes of NATURE which propped up the camera. The success was really a downright "fluke"; for, knowing the exposure must be hundreds of times too much, I added a quantity of bromide of potassium to the developer, and the amount chanced to be correct. All photography is done with objective and camera. In photographing the sun, the object is some ninety millions of miles off; in photographing a fluid inclusion in quartz, it is the 1/16th of an inch off—a mere question of detail. Most of these scientific photographs are far easier than the simplest everyday landscape.

A. R. Hunt.

### Comets and Corpuscular Matter.

Referring to Prof. J. J. Thomson's article on "corpuscles" in your issue of May 10, it occurs to me that the behaviour of corpuscular matter described therein may have some bearing on cometary phenomena. May not the structure of comets to some extent be explained by assuming that their tails are composed of aggregations of negatively charged particles of extremely minute size, answering to the free corpuscular matter as defined by Prof. Thomson, and which to a large degree may be formed by a sort of "corpuscular dissociation," or detachment, taking place in the comet's nucleus when its temperature is elevated upon nearing the sun? Since Prof. Thomson's experiments indicate the presence of negatively charged matter in kathode rays having a much smaller mass than ordinary atoms, there is reason to believe that matter in this state has properties quite apart from matter in a much coarser state of atomic division. Postulating an electrostatic field as existing in interplanetary space, with the sun as a negative centre or source of electrostatic radiation, and assuming that a comet's tail is composed of these corpuscles, the gravitational force it may suffer, when in proximity to the sun, would perhaps be very small in comparison with the electrostatic force existing throughout the vast congregation of these extremely minute particles, and thereby account for the repulsion of the tails of comets when they approach the sun.

The nuclei of comets may be composed of matter in a much coarser state of subdivision, which, though endowed with positive or opposite electricity, is subject to gravitational influences which determine their course in the neighbourhood of the sun.

While the above is a partial re-statement of existing hypotheses, it may, I venture to suggest, be of interest in connection with Prof. Thomson's remarkable experiments on matter smaller than atoms.

F. H. Loring.

1 Champion Grove, Denmark Hill, S.E., May 18.

## *A NEW INSTRUMENT TO MEASURE AND RECORD SOUNDS.*[1]

A DIRECT, absolute measurement of the intensity of sound at any point in the air must determine in ordinary units, such as kilogram-metres, the energy involved in the condensations and rarefactions of which the propagation of sound consists. But these pulsations follow each other so rapidly, and the amount of energy involved in even the loudest sound is so infinitesimal, that such measurement is attended with considerable difficulty; so much, indeed, that probably not a half-dozen laboratories in the world have any instrument whatever purporting to make direct, absolute measurements of the energy of sound.

We owe to Helmholtz ("Wissenschaftlische Abhandlungen," vol. i. p. 378) a mathematical theory by which we can determine the ratio between the energy of the pulsations of a tone just without, and that within a spherical Helmholtz resonator; to Lord Rayleigh we owe an expression for the energy of sound in terms of the condensation ("Theory of Sound," vol. ii. Sec. 245). Upon these two results this instrument (like Wien's, *Wied. Ann.* 1898, p. 834) is founded.

A pure tone is received into a spherical Helmholtz resonator, a portion of the walls of which is replaced by a small, circular, extremely thin glass plate, situated just opposite the mouth of the resonator. The pulsations within force this plate to vibrate with the tone's frequency; and if the natural pitch of the plate is made to approximate that of the resonator and tone, the amplitude of the plate's vibrations are rapidly multiplied. To make this amplitude a definitely measurable quantity, the sensitive plate carries at its centre a tiny mirror, which forms one of a system of mirrors constituting Michelson's refractometer (*Phil. Mag.* 1882, xiii. p. 236). A displacement of the little mirror from its position at rest amounting to a half wave-length of light will cause a corresponding shifting to one side of the interference bands, so that each dark band will take the position before occupied by the next dark band. The width of the bands may be so adjusted that a telescope with micrometer eyepiece can easily subdivide each band into a hundred parts. Hence the displacement of the sensitive plate, while a tone is sounding, could be observed with great precision, if the eye could act with sufficient rapidity to mark the oscillation of any one band.

That, of course, is out of the question. But it is easy to compound this motion of the bands with another motion perpendicular to it (also in the focal plane), and thus to make the displacements visible. To do this, the interference bands are made to stand vertically in the field, and a screen with a narrow, horizontal slit is interposed in the line of sight; consequently the bands during silence appear in the telescope as a narrow, horizontal strip, composed of the bands reduced to square spots of dark and light. Now a small lens, forming the object-glass of the telescope, is mounted upon the end of one tine of a tuning fork, electrically driven, and having the pitch of the tune to be measured. During silence, the vertical vibration of the object-glass stretches out the strip of spots into a rectangle of long, vertical bands. But when the tone sounds, these bands arrange themselves diagonally across the same rectangle, the slope of the bands increasing with the intensity of the tone.

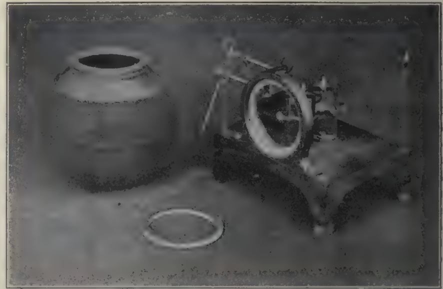

Fig. 1.—The refractometer. The resonator has been unscrewed from the supporting bracket, leaving the sensitive plate and tiny mirror in place.

The micrometer eyepiece can be rotated on its optical axis, and it is provided with a tangent screw for close adjustment. As it is rotated a vernier moves over a graduated arc, so that the angle of the slope ($a$) may be measured, as well as the height (Q) of the rectangle, the height ($o$) of the strip, and the width of five double bands. Putting $B = Q - o$, and P = the displacement of a band, we have $P = B \tan a$. The intensity of the tone is proportional to $P^2$, which is thus determined in mean wave-lengths of white light.

Thus far it has been tacitly assumed that the source of tone is at just the right distance from the receiving resonator for the vibrations of the sensitive plate to be in phase with those of the fork carrying the object-glass. But in ordinary work this agreement in phase rarely occurs, so a further modification is important. However, by simply loading the lens fork very slightly, we make the phases of the one oscillation overtake those of the other as slowly as we please. During agreement in phase the appearance of the bands will be that already described, with the slope (let us say) downward to the right. Two or three minutes after, when the two phases are opposite, the slope of the bands will be downward to the left. Between these two appearances confusion will reign, for the rectangle is then occupied by overlapping ellipses of changing eccentricity. But whenever the two oscillations are composed into a straight line there is abundance of time to measure the slope of the interference bands.

---

[1] This instrument is described somewhat more fully than it is here in the *Monthly Weather Review*, July 20, 1899, published by the U.S. Department of Agriculture. We are indebted to the courtesy of its editor, Prof. Cleveland Abbe, for the accompanying illustrations.

We have now attained only a relative measurement of intensity. But if we knew what maximum pressure within the resonator produced the observed amplitude of the sensitive plate, Rayleigh's expression together with Helmholtz's ratio would yield us the absolute intensity of the tone just outside the mouth of the resonator, which we seek. This pressure we do not know; we can, however, make a pretty close approximation to it. Let us be content, provisionally, with an error of about four parts in a thousand. Accordingly we will remove the sensitive plate from the resonator, in order to substitute for it a thicker plate, of natural pitch four octaves higher. Then we will cork the resonator, and produce a series of pressures within it by means of an air-pump. These pressures, measured statically with a water manometer, together with the corresponding displacements, furnish a table of the degree of approximation sought; so that by interpolation, when necessary, we may assign the pressure that has caused the amplitude, P, in any particular case, and thence obtain the energy of the tone in absolute units.

Of course, much pains must be taken to exclude all disturbing vibrations from the sensitive plate, whether transmitted through the air or through the floor and supports. Moreover, even the waves of the tone to be measured must be allowed to beat only upon the side of the plate which is within the resonator. Accordingly, heavy, padded boxes and piers of soft rubber are employed for the refractometer, for the tuning fork which carries the object-glass; and also for the instrument which produces the tone, as well as for the camera, both of which remain to be described. With these precautions, however, the result desired is very well attained, as is shown by careful tests. Moreover, the constancy and sensitiveness of this instrument promise to be highly gratifying.

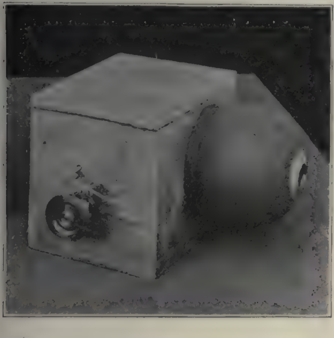

FIG. 2.—The refractometer boxed and ready for use. The resonator is covered with felt.

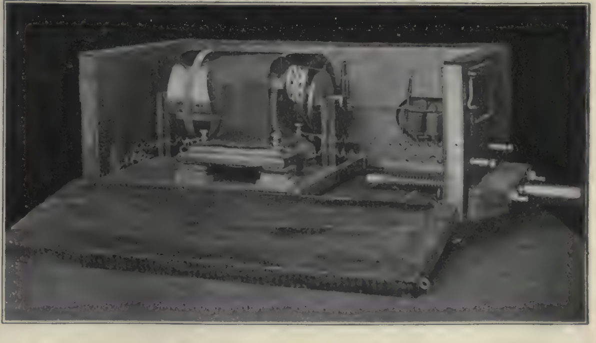

FIG. 4.—The open camera. The motor is shrouded to prevent its sparking from fogging the film. Adjustment of speed is accomplished by the aid of stroboscopic observation of the disc of black and white sectors, inspected through the square of ruby glass opposite. The electromagnet operates the arm which carries the shutter.

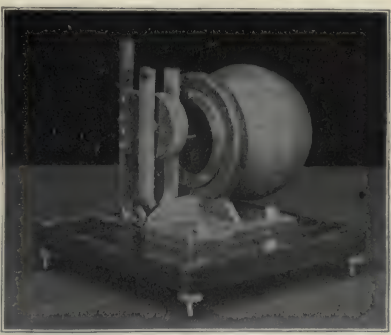

FIG. 3.—The source of tone, with its box removed.

For experimentation we require a source of sound that will produce a tone of great constancy and purity, but one whose intensity may be varied at will between wide limits. Moreover, the tone should issue from a small and definitely located area. It will be convenient, also, to have this instrument easily portable, so that it may be moved freely even while sounding. Such a source is obtained by causing a tuning fork to transmit its vibrations to a thin iron plate, which forms a portion of the walls of another spherical resonator; for the middle of one tine is rigidly connected with the centre of the plate. This combination is carefully tuned to give the tone required, and it is boxed so that only the mouth of the resonator protrudes. The fork is driven electrically, but its current is interrupted by the vibrations of a second fork, the two being in relay. The intensity of the tone depends, of course, upon the strength of the current which drives the source-fork, and this we may vary at will. Moreover, the intensity at the mouth of the source-resonator may be defined in terms of the current effective in producing it. These intensities are determined by means of the damping factors of the arrangement. The theory of this source as an independent, absolute measure of intensity is an extension (Sharpe, *Science*, 1899, p. 810) of that given by Lord Rayleigh for the tuning fork (*Phil. Mag.* 1894, vol. xxxviii. p. 365). This instrument makes a very pure and effective source of tone, simple in construction, and useful for a variety of purposes. A feeble current of a few hundredths of an ampere produces a tone that can be distinctly heard in every part of a building, 204 × 114 feet, four stories high, and containing ninety rooms. It may also be used under water.

To photograph and thus record for analysis a sound of any kind whatever, the resonator is removed by simply screwing it off, without disturbing the sensitive plate; and a camera is substituted for the telescope and eye. The window of the camera now forms the narrow slit, and a lens, placed between the window and the refractometer, focuses a narrow, horizontal strip of interference bands upon the photographic film. This film is wound about a cylinder (*cf.* Raps, *Wied. Ann.* 1893, p. 194) kept in rapid rotation by a small electric motor within the camera. The speed of this motor is kept constant by Lebedew's method (*Wied. Ann.* Band 59, p. 118). Consequently the lateral vibration of the bands caused by the sound, combined with the steady, vertical motion of the exposed portion of the film, is recorded in parallel, wavy lines. The shutter is opened for the time required for a single rotation of the cylinder by an electrical device. After each exposure the cylinder is moved in the direction of its axis by turning a screw from without. Thus a fresh portion of the film is brought under the shutter, without stopping the motion or opening the camera. In this way were taken the photographs of fork tones and vowels here given (Fig. 5). The photograph of a single tone from the source, whose intensity at the sensitive plate has been determined by the first method, affords a standard (viz. its amplitude) for determining the absolute intensity of every other sound photographed; while comparison with the wave-length appearing in the photograph of the tone of a standard fork gives the pitch of other sounds.

## NOTES.

As we go to press, a message from Sir Norman Lockyer at Santa Pola informs us that 130 volunteer observers have been obtained from H.M.S. *Theseus*, the instruments have been adjusted, and the Spanish authorities are assisting splendidly. The weather prospects are good.

MR. J. S. BUDGETT left Liverpool on Saturday last on his second expedition to the Gambia, where he is going in order to complete his studies of the fish-fauna of that colony, and especially to investigate the life-history and development of the abnormal fishes *Polypterus* and *Protopterus*. On reaching Bathurst, Mr. Budgett will proceed up the River Gambia to his former quarters on M'Carthy's Island, in the neighbourhood of which he has already ascertained that these fishes are found breeding during the rainy season. A memoir on some points in the anatomy of *Polypterus*, based on specimens obtained by Mr. Budgett during his first expedition, was read before the Zoological Society on May 8, and will shortly be published in the Society's *Transactions*.

AT a recent meeting of the British Ornithologists' Union and Club, under the presidency of Mr. F. D. Godman, F.R.S., the following resolution was unanimously adopted:—"That any member of the union directly or indirectly responsible for the destruction of nests, eggs, young or parent birds of any species mentioned below should be visited with the severest censure of the union and club." The birds referred to are the chough, golden oriole, hoopoe, osprey, kite, white-tailed eagle, honey buzzard, common buzzard, bittern and ruff.

THE committee of the Liverpool School of Tropical Diseases have decided to despatch, at an early date, an expedition to the Amazon to investigate yellow fever. The expedition will probably in the first instance proceed to Baltimore to confer with the yellow fever experts at the Johns Hopkins University, afterwards going to Para and other places on the South American coast.

An expedition, under the auspices of the Royal Dublin Society and the Royal Irish Academy, conjointly, has left Dublin for Spain, to observe the solar eclipse on May 28. The party consists of Prof. C. J. Joly, Sir Howard Grubb, F.R.S., Dr. A. Rambaut, F.R.S., Mr. W. E. Wilson, F.R.S., Prof. W. Bergin, Mr. S. Geoghegan and Mr. Rudolph Grubb. The observers have selected as their station the hill of Berrocalillo at Placencia, near Madrid, and have already had valuable assistance afforded them by Prof. Iniquez, director of the Observatory at Madrid, and his staff, who will themselves observe the eclipse at the same station.

Palæontologists will be glad to know that the King of the Belgians has just made M. L. Dollo, Conservator of the Brussels Museum, a Chevalier of the Order of Leopold.

The annual meeting of the Italian Botanical Society will be held at Venice on September 9-15, under the presidency of Sig. Sommier.

The committee of the International Botanical Congress, to be held in Paris from October 1 to 10, has issued a fresh invitation to foreign botanists to enrol themselves as members. The subscription fee of members has been fixed at 20 fr., which will include the cost of the publications of the Congress. The following have already been fixed on as subjects for discussion at the Congress:—Monographic studies; species and hybrids; unification of micrometric measures; influence of the nature of the soil, and of the plants growing in it, on the development of fungi; and other suggestions are invited. The president of the Congress will be M. E. Prillieux; the general secretary, M. E. Perrot; and the treasurer, to whom subscriptions should be sent, M. H. Hua, rue de Villersexel 2, Paris.

A departmental committee has been appointed to inquire into the conditions under which agricultural seeds are at present sold, and to report whether any further measures can with advantage be taken to secure the maintenance of adequate standards of purity and germinating power. The committee consists of the following members, viz.:—The Earl of Onslow, G.C.M.G., chairman; Sir W. T. Thiselton-Dyer, K.C.M.G., C.I.E.; Sir Jacob Wilson; Mr. R. A. Anderson, secretary of the Irish Agricultural Organisation Society; Mr. R. Stratton; Mr. Martin J. Sutton; Mr. James Watt and Mr. David Wilson. Mr. A. E. Brooke-Hunt, of the Board of Agriculture, will act as secretary to the committee.

An excursion to Malvern and district has been arranged by the Geologists' Association for Whitsuntide. The director will be Prof. T. T. Groom, and during the stay at Malvern, from Saturday, June 2, to Tuesday, June 5, a number of interesting geological sections and structures will be examined.

The tenth International Congress of Hygiene and Demography will be held in Paris this year, on August 10-17, under the presidency of Dr. Brouardel, Dean of the Faculty of Medicine of Paris. Programmes and forms of application for membership can be obtained from the secretary of the British Committee, Dr. Paul F. Moline, 42, Walton Street, Chelsea, S.W.

A meeting of the Institution of Mining Engineers will be held in London on June 14-16. The members have been invited to attend the International Congress of Mining and Metallurgy which will be held in Paris on June 18-23, with the object of collecting together engineers and others, who in various parts of the world are engaged in forwarding the progress of mining and metallurgy. The Congress, like that of 1889, is under the direct patronage of the French Government.

Swedish metallurgy has suffered a severe loss by the death, on May 12, of Mr. G. F. Göransson, at the age of eighty-one. Without his help, the Bessemer process might perhaps never have been perfected. In 1858, at Edsken, he increased the area of the tuyeres, and succeeded in shortening the process so as to produce sufficient heat in the converter to allow of the proper separation of the slag from the metal, and thus to convert pig-iron into good steel, which having been exported to England encouraged the capitalists who were supporting Sir Henry Bessemer. At the Swedish meeting of the Iron and Steel Institute in 1898, Mr. Göransson, although very infirm, welcomed the members, in an English speech, to the Sandvik works, of which he was chairman and founder.

At the anniversary meeting of the Royal Geographical Society, on Monday, the medals and other awards already announced (p. 34) were presented. The president, Sir Clements Markham, in the course of his anniversary address, said that a committee has been formed to obtain funds for the erection of a suitable memorial to Dr. Livingstone, on the spot where the tree stood under which the heart of the great explorer was buried. The materials will be conveyed, free of expense, from the mouth of the Zambesi to Lake Bangweolo, by the kindness of the African Lakes Corporation and the British South Africa Company. The prospects of the Antarctic expedition, from a financial point of view, have been somewhat clouded by the war. At least 30,000*l*. more than has already been raised is required. Apart from the finances, the affairs of the expedition are in a flourishing state, and everything seems hopeful. The keel of the exploring ship is now laid at Dundee. She will be the best polar exploring vessel that has ever left these shores, and the first that has ever been built in this country specially for scientific work in polar regions.

We regret to record the death, at the age of seventy-seven, of Mr. James Thomson, F.G.S., of Shawlands, Glasgow. Among the many enthusiastic workers at Scottish geology, none had plied his hammer with more zeal. He had been an active member of the Geological Society of Glasgow for upwards of forty years, and was a frequent attendant at the meetings of the British Association. Although he had written on the geology of Islay, and on parts of Arran and the Outer Hebrides, his special researches were on the Scottish Carboniferous corals; and his contributions on this subject, carried on partly in conjunction with the late Prof. H. A. Nicholson, were numerous. He had formed an exceedingly fine collection of fossil corals, which he presented to his native town, Kilmarnock.

A possible method of prevention of horse-sickness, which is endemic in the Orange Free State, Transvaal, Natal, Rhodesia and Bechuanaland, and also occasionally occurs in Cape Colony, is described in the *Cape Times* (April 24) by Dr. G. C. Purvis. Fortified serum, derived from immune horses, almost invariably produces fatal hæmoglobinuria when injected into horses suffering from horse-sickness. Dr. Purvis finds, however, that if the animal is gradually accustomed to the toxin, until it can receive an injection of 100 c.c. or 200 c.c. of serum, virulent blood can be injected without danger. It appears that fortified serum is a useful agent if used in a proper way, and that it is capable of preventing the onset of horse-sickness. Moreover, if, in spite of precautions, an animal acquires the disease, judicious treatment with the serum will assist in bringing about a cure.

A BACTERIOLOGICAL method of exterminating rats, proposed by M. J. Danysz of the Pasteur Institute of Paris, is described in the *British Medical Journal*. M. Danysz has found a microbe which, if introduced into a population of rats, may be trusted to breed a pestilence among them that will wipe them out, or at least make them a negligible quantity. From field-mice suffering from a spontaneous epidemic disease he isolated a cocco-bacillus presenting the general characters of *B. coli*, and thus resembling Lœffler's *B. typhi murium*. By an elaborate process of repeated cultures of this micro-organism passed through series of mice and afterwards through rats, he succeeded in intensifying its virulence so as to make it, when eaten, certainly pathogenic for the latter rodents. Having satisfied himself of the fatal effect of the cultures in the laboratory, he had them tried in a large number of farms, warehouses, and other places infested by rats. From the reports of these experiments, amounting to several hundreds, it appears that in 50 per cent. of cases the method resulted in a complete disappearance of the rats, while in 30 per cent. their number notably diminished; in 20 per cent. the method failed.

SOME interesting figures showing the high estimation in which technical knowledge is held in certain branches of industry by German manufacturers, have recently been published in the *Zeitschrift für angewandte Chemie*, from a lecture on "Technical Education and the Importance of Scientific Training," delivered before the German Emperor by Prof. J. Bredt. The following statistics, corrected to the end of last year, refer to three of the most important factories in Germany where aniline dyes are made, viz. the Badische Anilin-und Sodafabrik, of Ludwigshafen; the Farbewerke vorm. Meister Lucius und Brüning, of Höchst am Main; and the Farbenfabriken vorm. Fr. Bayer and Co., of Elberfeld.

| | Ludwigshafen. | Höchst. | Elberfeld. |
|---|---|---|---|
| Workmen | 6207 | 3670 | 3900 |
| Staff | — | 128 | 886 |
| Chemists | 146 | 130 | 130 |
| Engineers | 75 | 37 | 29 |

Of course, the *Engineer* remarks, conditions are somewhat different in Germany from those which obtain in this country, because these dye works own the patents for various highly lucrative proprietary articles, and manufacture numerous pharmaceutical preparations; but we should be interested to learn how many "chemical" factories in Great Britain employ over 100 skilled chemists.

AN enterprise, similar to the Edison works at Paderno, where energy of some 13,000 horse-power is derived from the River Adda, and employed for producing electricity, which is carried by overhead cable to Manzo and Milan, but on a larger scale, is, states the *Board of Trade Journal*, now on the eve of completion in Northern Italy. A report of H.M. Consul at Milan (*Foreign Office, Annual Series*, 2413) states that the Società Lombardia per distribuzione di energia Elettrica, obtained a concession from the Government on the River Ticino, at Vizzola, some miles below its issue from Lake Maggiore, and immediately set about constructing works for the development of hydraulic power of no less than 20,000 horse-power (theoretical), which will give 10,000 effective horse-power of electric energy for industrial purposes, after making full allowance for loss in transmission. Since the works were begun, the sanction of the Government has been obtained to a project for the construction of a movable dam across the river some distance higher up, which would enable the company to increase its volume of water, and allow of the same being constantly maintained during all seasons of the year. The theoretical hydraulic power would then be 24,000 and the effective electric energy 12,000 horse-power. This dam has not yet been commenced, but the works have been constructed on the basis of the larger supply of water. Seven turbines and seven dynamos, giving three-phase alternating currents, have been put up. The dynamos and all the other electrical plant have been supplied by Germany. It was originally intended to bring all this electric energy into Milan, a distance of twenty-five miles, but the whole of it has now been disposed of in and about the manufacturing towns of Gallarate, Busto, Arsizio, Legnano and Sarsuno, which lie between Vizzola and Milan, a district which already, for the cotton industry alone, uses steam to the extent of 10,000 horse-power. This enterprise is said to be the most important of its kind in Europe. The plans are due to the initiative of Italian engineers and were made as far back as 1887, but their execution must be attributed in a large measure to the assistance of a German firm which has subscribed a considerable part of the capital of the company.

IN a recent number of NATURE (March 1, p. 421) reference was made to a paper by Dr. Lüdeling, in which diurnal variations of terrestrial magnetism were shown graphically "with the aid of von Bezold's vector diagrams." Though von Bezold appears to have been the first to use the convenient term "vector diagram" to designate the curves referred to, Dr Chree pointed out in NATURE of March 22 (p. 490) that the curves were employed by Airy in 1863, and since then by several people in this country, including Lloyd and himself, and were not used by von Bezold until 1897. Dr. Lüdeling now sends us a letter in which he states that both von Bezold and himself were well aware of the previous use of the curves, and that acknowledgment of earlier work was made in the paper briefly mentioned in NATURE.

PROF. J. JOLY has discussed "The Theory of the Order of Formation of Silicates in Igneous Rocks" (*Proceedings*, Roy. Dublin Soc. ix. [N.S.] 1900). He has lately found that the softening point of quartz is far below what is currently thought. Observations indicate that silica is a body possessing an extraordinary range of viscosity. It is a thick liquid at about 1500° C. At a temperature of about 800° C. it is plastic, and yields with considerable rapidity to distorting forces. Perhaps it never crystallises very vigorously. The author's experiments show that a silicate containing a small quantity of silica crystallises out at a higher temperature than a silicate with a larger percentage of silica; and this, according to his theory, is because the crystallising point of the one is less affected by the silica than that of the other.

IN a short article on "The Formation of Minerals in Granite" (*Memoirs*, Manchester Lit. and Phil. Soc. xliv. 1900), Mr. C. E. Stromeyer brings forward some facts and suggestions which lead him to conclude that there is no necessity to limit the temperature of granite formation, as propounded by Dr. Sorby, nor to assume that the earth's interior is solid. Not only temperature and rate of cooling, but also pressure have combined to influence the mineral composition of granites. Where the solid rock resting on the molten material is of a low specific gravity and a bad conductor of heat, the depth at which granite rock would commence to solidify would not be great, and most probably the quartz would crystallise first, forming, say, quartz-porphyry. Where the rock resting on the molten mass is heavy, containing perhaps much iron-oxide, and acting as a good conductor of heat, the depth at which the granite would commence to solidify would be much greater than in the previously-mentioned case, the pressure would be much greater, and most probably the quartz would remain fluid long after the felspars had crystallised, forming, say, felspar-porphyry. In the author's opinion, every intermediate condition is conceivable.

The second volume of the *Annales* of the National Observatory of Athens contains a catalogue of the earthquakes felt in Greece during the years 1893-1898. Its value will be evident from the facts that it occupies more than 150 quarto pages and contains entries of 3187 shocks. Taking area into account, it therefore appears that earthquakes are about twice as frequent in Greece as they are in Japan. M. Eginitis, the director of the observatory, adds an interesting discussion of the catalogue. For the six years of the records, earthquakes were most numerous during the months of April and May; there is the usual apparent maximum during the early hours of the morning; and the usual doubt as to the existence of any connection between the frequency of earthquakes and the positions of the earth and moon in their orbits. There seems to be no part of the country entirely free from earthquakes, but their distribution is most irregular, 2018 shocks having been recorded in Zante alone. The volume also contains the meteorological tables for 1896, and essays by M. Eginitis on ancient observations of meteor showers, the increase of the discs of the sun and moon at the horizon, and the solar eclipse of August 8, 1896.

Two observers in the May number of the *Zoologist* note the effect of the unusually cold and late spring on the bird-life of the country. Mr. W. W. Fowler states that after a careful search, on April 10, in the neighbourhood of Chipping Norton, he was unable to discover a single specimen of the summer migrants which ought by that time to be numerous. Mr. W. Wilson, on the other hand, comments on the late pairing of lapwings and partridges in Scotland.

In the April number of the *Victorian Naturalist*, Mr. D. Le Souef gives an interesting account of the plants and animals met with during a visit to Western Australia. In several passages he comments on the diminution in the number of wild mammals. The rabbit-bandicoot, for example, has disappeared from districts where it was formerly numerous, owing to "ringing" the timber and cultivation; while the common phalanger, or "opossum," has been practically exterminated from the settled districts.

To the *Revue générale des Sciences* of May 15, Monsieur P. Glangeaud contributes a notice of the biological laboratory recently established among the extinct volcanoes of the Auvergne. The principal object seems to be the investigation of the fauna and flora of the numerous lakes, several of which are of great depth and cover a large area. Already important observations have been made with regard to the "plankton" of the lakes. On the salt plains the existence of a marine fauna has long been known, and the discovery is now announced of the survival there of a marine fauna.

We have received the fourth number of the *News Bulletin* of the Zoological Society of New York, which contains a popular illustrated account of some of the new buildings in the menagerie, as well as of several of the most notable animals. Some of the photographs, especially those of polar bears, of a group of wapiti (elk), and of a bull bison, are exquisite productions. We are, however, sorry to note that there is a deficiency of funds for the support of the zoological park; and an earnest appeal is made by the Board of Managers to induce more of the residents of New York to become members of the Society.

Mr. J. K. Barton has sent us a copy of a paper on the anatomy of the digestive tract of the salmon, published in the April number of the *Journal of Anatomy and Physiology*. The object of the investigation was to determine the truth of the statement that when salmon enter our estuaries they are suffering from a degenerative catarrh of the mucous membrane of the intestines, which subsequently spreads upwards to the stomach. The examination of a considerable number of specimens is stated to refute this assertion, and that previous observers have been misled by the effects of the methods employed in their investigations.

Part III. of "A Manual of Surgical Treatment," by Dr. W. Watson Cheyne, F.R.S., and Dr. F. F. Burghard, has been published by Messrs Longmans, Green and Co. The subject is the treatment of the surgical affections of the bones, and amputations. We propose to review the work when the six parts of which it will be composed have been published.

The fifth revised and enlarged edition of Dr. Richard Hertwig's "Lehrbuch der Zoologie" has just been published by the firm of Gustav Fischer, Jena. As with other zoological text-books, many alterations and additions have had to be made in order to bring it in touch with the present state of knowledge.

The material collected by Dr. Arthur Willey from New Britain, New Guinea, Loyalty Islands and elsewhere, when in search of the eggs of the Pearly Nautilus, during the years 1895-97, has proved exceptionally rich in subjects of study. Part iv. of the "Zoological Results" (Cambridge: University Press) contains ten papers upon various forms of life, and Part v. is in the press. The original intention was to complete the work in five or six parts.

A new sugar has been discovered by M. Gabriel Bertrand, by the action of the sorbose bacterium upon erythrite, and is described by him under the name of erythrulose in the *Comptes rendus* for May 14. By its reactions it appears to be a ketone of the composition $CH_2(OH).CO.CH(OH).CH_2OH$, thus being a lower homologue of levulose. Erythrulose is not fermentable by yeast, but forms a well crystallised osazone; it resists oxidation by bromine water, and hence is probably a ketone.

A new general method of preparing secondary and tertiary alcohols, which, on account of the excellent yields obtainable, promises to be of considerable service, is described by M. V. Grignard in the current number of the *Comptes rendus*. Magnesium turnings react but slowly with methyl iodide at ordinary temperatures, but in presence of ether a violent reaction takes place, resulting in a clear solution probably containing $CH_3.MgI$. If to this solution an aldehyde or ketone is added, and the product treated with dilute acid, about 70 per cent. of the theoretical amount of the corresponding secondary or tertiary alcohol can be isolated. Thus methyl iodide and acetaldehyde give isopropyl alcohol; benzaldehyde and isobutyl bromide give phenylisobutyl-carbinol; methyl iodide and acetophenone, dimethyl-phenyl-carbinol.

The additions to the Zoological Society's Gardens during the past week include a Squirrel Monkey (*Chrysothrix sciurea*) from Guiana, presented by Mr. Percy L. Isaac; an Ocelot (*Felis pardalis*) from South America, presented by Mr. M. A. French; an Allen's Porphyrio (*Hydrornia alleni*) captured at sea, presented by Captain J. C. Robinson; a Snowy Owl (*Nyctea scandiaca*, ♀) from Bylott Island, Lancaster Sound, presented by Mr. A. Barclay Walker; two Long-eared Owls (*Asio otus*), European, presented by Mr. D. F. Campbell; six Long-nosed Crocodiles (*Crocodilus cataphractus*) from West Africa, presented by Mr. J. S. Budgett; four Blood-rumped Parrakeets (*Psephotus haematonotus*), two Rose Hill Parrakeets (*Platycercus eximius*), two Crested Pigeons (*Ocyphaps lophotes*), two Plumed Ground Doves (*Geophaps plumifera*), two Black and White Geese (*Anseranas semipalmata*) from Australia, two African Tantaluses (*Pseudotantalus ibis*), two Senegal Touracous (*Turacus persa*) from West Africa, purchased; two King Snakes (*Coronella getula*), a Coralline Snake (*Coronella gentilis*), two American Black Snakes (*Zamenis constrictor*), ten Pennsylvanian Mud Terrapins (*Cinosternum pennsylvanicum*), four Adorned Terrapins (*Chrysemys ornata*), thirteen Elegant Terrapins (*Chrysemys scripta elegans*), six Lesueur's Terrapins (*Malacoclemmys lesueuri*), six Red Newts (*Sperlepes ruber*) from North America, a Garnett's Galago (*Galago garnetti*) from East Africa, a Serval (*Felis serval*) from Africa, a Common Teguexin (*Tupinambis teguexin*), three Annulated Terrapins (*Nicoria annulata*) from South America, four Blue Wall Lizards (*Lacerta muralis*, var. *cœrulea*) from Faraglione, five Schlagintweit's Frogs (*Rana cyanophlyctis*) from Southern Asia, deposited; a Barbary Wild Sheep (*Ovis tragelaphus*, ♂), born in the Gardens.

## *OUR ASTRONOMICAL COLUMN.*

THE DARK FRINGES OBSERVED DURING TOTAL SOLAR ECLIPSES.—We have received a communication from Señor V. Ventosa, astronomer at the Madrid Observatory, concerning the appearance and probable cause of the dark fringes—or "shadow bands" as they are generally called—which are always observed some few seconds before and after totality during the progress of a total eclipse of the sun. The chief points of his communication are here summarised.

These alternating dark and bright fringes are parallel to each other, all moving in the same direction, but the velocity varies greatly from time to time. Several reasons have been advanced to account for their appearance, chief of which are those regarding them as (1) diffraction fringes bordering the actual shadow of the moon on the earth's surface; (2) shadow phenomena produced in the body of our own atmosphere, and affected by the direction of the wind. The examination of the observed facts appears to support to some extent those holding the latter view, as while the bands may be well seen in one place, they may be invisible in a neighbouring locality; their form, generally rectilinear or slightly undulating, is also variable, while their breadth has been variously estimated from 1 cm. to 50 cm., although this will, of course, partly depend on the inclination of the surface on which they are observed. Sometimes they move with about the speed of a man walking, at others with the speed of an express train, the velocity always being less, however, than that of the shadow itself. (During the coming eclipse the shadow will move through 800 kilom. in 12 minutes.)

Señor Ventosa has been occupied for some time in studying the currents in the higher regions of our atmosphere by observing the undulations round the sun and stars with a telescope, and thinks that these upper atmospheric currents may possibly have some bearing on the question of the eclipse shadow bands; the movement of these higher portions showing through the quieter lower strata and being rendered visible on account of different refractive powers. He thinks it would be useful to determine the velocity of these currents by anemometers at various altitudes, and also to observe the undulations round the limb of the sun at the time of eclipse, comparing them with the shadow bands in direction and velocity of movement. To ascertain if any experimental illustration of this hypothesis could be presented, he states that bands may be produced by passing diffuse light reflected from a sheet of corrugated glass through a circular aperture representing the sun, over which an opaque disc, representing the moon, is made to slide. When the segment left uncovered is about 5 mm. in width, alternate bright and dark bands can be observed on a white screen held near, if the length of the segmental opening is approximately parallel to the undulations of the glass, but if at right angles they entirely disappear. He trusts, however, that his putting forward this hypothesis for establishing a connection between eclipse shadow bands and atmospheric undulations will show the advisability of recording the direction and velocity of the wind during eclipses, so that more definite data may be available for discussion.

PHOTOMETRY OF CORONA, APRIL 16, 1893.—In a communication recently made to the Royal Society, Prof. H. H. Turner, F.R.S., gives the details of procedure and results obtained in photometric observations of the corona during the total eclipse of the sun in April 1893. The visual brightness of the corona was determined by Prof. T. E. Thorpe at the eclipses of 1886 August 29, and 1893 April 16, by a method arranged by Sir W. Abney (*Phil. Trans.* A, 1889, p. 363, and 1896, p. 433), but soon after the first of these, Sir W. Abney devised a method of comparing the coronal light with that of a fixed standard by photographic means. This method was first put into practice at the eclipse of 1889, and has been repeated systematically since. Part of the photographic plate, before being taken for eclipse use, is exposed to a graduated series of exposures from a standard source of light in the laboratory, and then without development is afterwards used to receive the impression of the corona, the part carrying the previous standard exposures being protected from further light action. On subsequent development there results a picture of the corona, and a series of squares of graduated densities on the same plate, so that the brightness of any part of the coronal structure may be directly compared with the brightness of the standard light of the laboratory.

The 1889 photographs have not yet been measured, but Prof. Turner has reduced several of the plates taken in 1893 by Sergeant Kearney at Fundium, Africa. These were obtained with the "double tube" apparatus, giving pictures of two sizes, the moon's disc being 0·6 inch and 1·5 inches in diameter. Examples of each scale image were examined, one of the large scale photographs, taken with an exposure of 50 seconds, being specially carefully measured along four radii extending due N., S., E., W., from the limb respectively, and the resulting table of comparison measures is included in the present paper. This table shows:—

(1) That the accuracy of the method is such that the intensity of the light is determinable within a very small error.

(2) The intensity of the coronal light falls off in nearly the same manner in all four directions (1893 was near a sun-spot *maximum*, with corona of symmetrical form). There is a marked difference, however, between the intensities along the north and south radii.

(3) The falling off in intensity is at first exceedingly rapid, becoming very gradual at distances more than 45 minutes from the limb.

(4) The absolute brightness of the corona in terms of the "moon" by using a conversion factor.

Prof. Turner then compares the brightness thus determined photographically with that obtained visually by Abney and Thorpe, and presents two curves showing the combined observations, which show a marked agreement between the results arrived at in such different ways. No measures of brightness, however, were made *visually* within 0·6 of a radius from the limb, and it would be useful if this were done at the coming eclipse.

MAXIMUM DURATION OF TOTALITY FOR SOLAR ECLIPSE.—Mr. C. T. Whitmell sends us the following corrections to the data given in the abstract of his paper last week (p. 64):—

Earth's radius to be taken as 3963·296 miles.
Moon's „ „ „ „ „ 1080·000 „

The eclipse for which the totality will be a maximum will take place at noon about the beginning, not the middle, of July.

## *SOME MODERN EXPLOSIVES.*[1]

NEARLY thirty years ago, in the Royal Institution, I had the honour of describing the great advances which had then recently been made both in our knowledge of the phenomena which attend the decomposition of gunpowder, and in its practical application to the purposes of artillery.

I described the uncertainty which up to that date had existed as to the tension developed by its explosion, the estimates varying enormously from the 101,000 atmospheres (about 662 tons on the square inch) of Count Rumford to the 1000 atmospheres (6·6 tons per square inch) of Robins, or, taking more modern estimates, from the 24,000 atmospheres (158 tons per square inch) of Piobert and Cavalli to the 4300 atmospheres (about 29 tons per square inch) of Bunsen and Schischkoff.

These uncertainties were, I think I may say, set to rest by certain experiments carried out both in guns and close vessels at Elswick, by the labours of the Explosive Committee appointed by the War Office, and by researches conducted by Sir F. Abel and myself. These researches were conducted on a large scale with the view of reproducing as nearly as possible in experiment the conditions that exist in the bore of a gun. You may judge of the magnitude of the experiments when I tell you that I have fired and completely retained in one of my cylinders a charge of no less than 28 lbs. of ordinary powder.

---

[1] A Discourse delivered at the Royal Institution on Friday, March 23, by Sir Andrew Noble, K.C.B., F.R.S.

The result of the discussion of the whole series of experiments led to the following conclusions :—

(1) That the tension of the products of combustion at the moment of explosion when the powder practically filled the space in which it is fired—that is, when the density is about unity—is a little over 40 tons on the square inch, or about 6400 atmospheres.

(2) Although changes in the chemical composition of powder, and even changes in the mode of ignition, cause a very considerable change in the metamorphosis experienced in explosion, as evidenced by the proportions of the products, the quantity of heat generated, and the quantity of permanent gases produced, being materially altered, it is somewhat remarkable that the tension of the products in relation to the gravimetric density is not nearly so much affected as might be expected from the considerable alteration in the above factors.

(3) The work that gunpowder is capable of performing in expanding in the bore of a gun was determined both by actual measurement and by calculation, and the results were found to accord very closely.

(4) The total potential energy of exploded gunpowder supposed to be fired at the density of unity was found to be about 332,000 gramme units per gramme, or 486 foot tons per lb. of powder.

I must confess that when I gave the lecture I have referred to, seeing the many centuries during which gunpowder has held its own as practically the sole propelling agent for artillery purposes, seeing also that gunpowder differs in certain important points from the explosives to which I shall presently call your attention, I had serious doubts as to whether it would be possible so far to modify these latter as to permit of their being used in large charges and under the varied conditions required in the naval and military services.

Gunpowder is not like gun-cotton, cordite, nitro-glycerine, lyddite, and other similar explosives, a definite chemical combination in a state of unstable equilibrium, but is merely an intimate mixture of nitre, sulphur and charcoal, in proportions which can be varied to a very considerable extent without striking differences in results. These constituents do not, during the manufacture of the powder, suffer any chemical change, and being a mixture it cannot be said under any condition truly to detonate. It deflagrates or burns with great rapidity varying very largely with the pressure and other circumstances under which the explosion is taking place, a train like that to which I set fire taking as you see an appreciable time to burn ; while, in the bore of the gun, a similar length of charge would be consumed in less than the hundredth part of a second.

You will further have observed the heavy cloud of smoke which has attended the deflagration you have seen. Nearly six-tenths of the weight of the powder, after explosion, remains as a finely divided solid, giving rise to the so-called smoke familiar to many of you, and of which a good illustration is shown in this instantaneous photograph. By way of comparison I burn similar lengths of gun-cotton in the form (1) of cotton, (2) of strand, (3) of rope, and you will observe the different rates at which these varied forms of the same material are consumed, the rate depending in this case upon the greater aggregation and higher density, consequently higher pressure, of the successive samples.

Although the names of cordite and ballistite are probably familiar to all of you, the appearance may not be so familiar, and I have here on the table samples of the somewhat Protean forms which these explosives, or explosives of the same nature, are made to assume.

Here, for instance, are forms of cordite, the explosive of the service, for which we are indebted to the labours of Sir F. Abel and Prof. Dewar. This, which is in the form of fine threads, is used in small arms, and here are successive sizes, adapted to successive larger calibres, until we reach this size which is that employed for the charge of the 12-inch, 50-ton guns.

A couple of the smaller cords I burn, both for purposes of comparison and to draw your attention to the entire absence of smoke.

The smoke of the gunpowder you see still floating near the ceiling, but little or no trace of smoke can be seen from such explosives as gun-cotton, cordite or ballistite, their products of combustion being entirely gaseous.

You will have observed that in the combustion which you have just seen there is no smoke, but I must explain, and I shall shortly show you, that this combustion is not quite the same as that which takes place, for instance, in the chamber of a gun. Here the carbonic oxide and hydrogen, which are products of explosion, burn in the air, giving rise, with the aid of a little free carbon, to the bright flame you see, and somewhat increasing the rate of combustion. In a gun, however, owing chiefly to pressure, the cordite is consumed in a very small portion of a second.

In order to illustrate the effect of pressure upon the rate of combustion, I venture to show you a very beautiful experiment devised by Sir F. Abel. It has been shown in this room before, but it will bear repetition.

In this globe there is a length of cordite. I pass a current through the platinum wire on which it is resting and you see the cordite burns. I now exhaust the air and repeat the experiment. The wire is red-hot, but the cordite will not burn. That the failure to burn is not due to the absence of oxygen is shown by plunging lighted cordite into a jar of carbonic acid, where, although a match is instantly put out, the cordite continues to burn—but observe the difference. There is no longer any bright flame, although the cordite is being consumed at about the same rate as when burned in air ; and when a sufficient quantity of the $CO_2$ is displaced, I can make the inflammable gases ignite and burn at the mouth of the jar.

Another illustration is also instructive. I have here a stick of cordite wrapped round with filter paper ; I dip it in water and light the end ; you may note that at first you see the bright flame. But as the combustion retreats under the wet filter paper, there appears a space between the flame and the cordite, the flame finally disappears, hot gases with sparks of carbon alone showing.

One other pretty experiment I show. I have here a stick of cordite which I light—when fairly lighted I plunge it in this beaker of water. The experiment does not always succeed at the first attempt, but you now see the cordite burning under the water much as it did in the jar of carbonic acid. The red fumes you observe are due to the formation of nitric peroxide caused by the decomposition of the water by the heat.

I have on the table samples of certain other smokeless explosives of the same class. Here is a ballistite used in Italy. Here is some Norwegian ballistite. Here again is ballistite in the tubular form, and in these bottles it is seen in the form of cubes. Here is some gelatinised gun-cotton in the tubular form, and here are some interesting specimens with which I have experimented, and which up to a certain pressure gave good results, but which exhibited some tendency to violence when that pressure was exceeded. Here also are some samples of the French B.N. powder, consisting of nitro-cellulose partially gelatinised and mixed with tannin, and with barium and potassium nitrates. Lastly, I show you here a sample of picric acid, a substance which has been used for many years as a colouring material, but which will be of interest to you because it is used as the explosive of lyddite shell, concerning which I shall presently have more to say ; it differs from all the other explosives in being, in the crystalline form, exceedingly difficult to light. I fuse, however, in this porcelain crucible, a small quantity. I pour a little on a slab, and on dropping a fragment into a red-hot test-tube you see with how much violence the fragment explodes. I also burn a small quantity, and you will observe that, unlike gun-cotton, cordite and ballistite, it is not free from smoke, the smoke in this case being simply carbonaceous matter. You will observe also how much more slowly it burns.

The composition of these various explosives (although in the case of both cordite and ballistite I have experimented with samples differing widely in the proportion of their ingredients) may be thus stated.

The gun-cotton I employed was of Waltham Abbey manufacture, and, when dried, consisted of 4·4 per cent. of soluble cotton and 95·6 per cent. of insoluble; as used, it contained 2·25 per cent. of moisture.

The service cordite consists of 37 per cent. trinitro-cellulose, with a small proportion of soluble gun-cotton, 58 per cent. of nitro-glycerine and 5 per cent. of the hydrocarbon vaseline.

The ballistite I principally used was composed of 50 per cent. dinitro-cellulose (collodion cotton) and 50 per cent. of nitro-glycerine. The whole of the cellulose was soluble in ether alcohol, and the ballistite was coated with graphite.

The French B.N. powder consisted of nitro-cellulose partly gelatinised, and mixed with tannin, and with barium and potassium nitrates. The transformation experienced by some of these explosives is given in Table I., while the pressures in relation to the gravimetric densities of some of the more important are shown in Fig. 1.

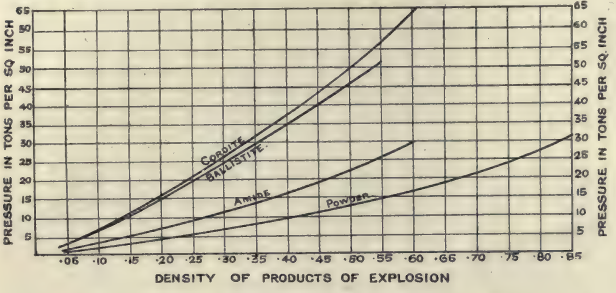

Fig. 1.—Pressures observed in closed vessels with various explosives.

Table I.

| Constituents | Cordite | Ballistite | B.N. | Lyddite |
|---|---|---|---|---|
| | vols. | vols. | vols. | vols. |
| $CO_2$ ... ... ... | 20·5 | 29·1 | 21·1 | 12·8 |

| Units of heat ... | 1272 | 1365 | 1003 | 856·3 |

The decomposition experienced by these high explosives on being fired is of much greater simplicity than that experienced by the old powders, and is, moreover, not subject to the considerable fluctuations in the ultimate products exhibited by them.

The products of explosion of gun-cotton, cordite, ballistite, &c., are at the temperature of explosion entirely gaseous, consisting of carbonic anhydride, carbonic oxide, hydrogen, nitrogen and aqueous vapour, with generally a small quantity of marsh gas.

The water collected, after the explosion vessel was opened, always smelt, occasionally very strongly, of ammonia, and an appreciable amount was determined in the water.

In examining the gaseous products of the explosion of various samples of gunpowder, it was noted that as the pressure under which the explosion took place increased, the quantity of carbonic anhydride also increased, while that of carbonic oxide decreased. The same peculiarity is exhibited by all the explosives with which I have experimented. I show in Table II. the result of a very complete series of a sample of gun-cotton fired under varying pressures, and it will be noted that the volumes of carbonic oxide and carbonic anhydride are, between the highest and lowest pressures, nearly exactly reversed.

Table II.

| Constituents | Under pressure of explosion, tons per square inch | | | | | | |
|---|---|---|---|---|---|---|---|
| | 2 tons | 8 tons | 12 tons | 18 tons | 20 tons | 45 tons | 50 tons |
| vols. | | | | | | | |
| $CO_2$ ... | 21·44 | 25·06 | 26·27 | 27·21 | 26·75 | 28·13 | 29·27 |
| CO ... | 29·66 | 26·31 | 25·08 | 25·24 | 24·53 | 23·19 | 22·31 |

| $CH_4$ ... | ·26 | ·41 | ·31 | ·77 | 1·47 | 2·46 | 2·70 |

There are slight changes as regards the other products, but they do not compare in importance with that to which I have referred.

But before drawing your attention to other points of interest, it is desirable to give you an idea of the advances in ballistics which have been made both by improvements in the manufacture of the old powders and by the introduction of the new.

On Fig. 2 is placed the results as regards velocity of nine explosives, commencing with the R.L.G. powder, which was in use in the latter part of the fifties, and terminating with the cordite of the present day.

The experiments I am now referring to were made in a gun of 100 calibres in length, and were so arranged that in a single round the velocities could be measured at 16-points of the bore. The chronoscope with which these velocities were taken has been already described, and I will now only say that it is capable of registering time to the millionth of a second with a probable error of between two and three millionths. One curious fact connected with the mode of registration I may mention. In the early experiments with the old powders, where the velocities did not exceed 1500 or 1600 feet-seconds, the arrangement for causing the projectile to record the time of its passing any particular point was effected by the shot knocking down a small steel knife or trigger which projected slightly into the bore; but when the much higher velocities, with which I subsequently experimented, were employed, this plan was found to be unsatisfactory, the steel trigger, instead of being immediately knocked down by the shot, frequently preferred instead to cut a groove in the shot, sometimes nearly its whole length, before it acted. Hence another arrangement for cutting the primary wires had to be adopted.

The diagram I am now showing you is, however, both interesting and instructive. The intention, among other points, was to ascertain for various calibres in length in a 6-inch gun the velocities and energies that could be obtained, the maximum pressures, whether mean or wave, not exceeding about 20 tons on the square inch. The horizontal line or axis of abscissæ represents the travel of the shot in feet, the ordinates or perpendiculars from this line to the curve represents the velocity at that point.

The lowest curve on the diagram gives, under the conditions I have mentioned, the velocities attainable with the powder which was used when rifled guns were first introduced into the service, and you will note that with this powder the velocity attained with 100 calibres was only 1705 foot-seconds, while with 40 calibres it was 1533 foot-seconds. Next on the diagram comes pebble powder with a velocity of 2190 foot-seconds; next comes brown prismatic with a velocity of 2529 foot-seconds.

The next powder is one of considerable interest, and one which might have arisen to importance had it not been superseded by explosives of a very different nature. It is called Amide powder, and in it ammonium nitrate is substituted for a large portion (about half) of the potassium nitrate, and there is also an absence of sulphur. You will observe the velocity in the 100 calibre gun is very good, 2566 foot-seconds. The pressure also was low and free from wave action. It is naturally not smokeless, but the smoke is much less dense and disperses much more rapidly than does the smoke of ordinary powder. Its great advantage, however, was that it eroded steel very much less than any other powder with which I experimented, while its great disadvantage was due to the deliquescent properties of ammonium nitrate necessitating the keeping of the cartridges in air-tight cases.

Next on the diagram comes B.N. or Blanche Nouvelle powder, an explosive which, while free from wave action, is remarkable, as you will note if you follow the curve, in developing a much higher velocity than the other powders in the first few feet of motion, and less in the later stages of expansion.

Thus, if you compare this curve with the highest curve on the diagram, that of the four-tenths cordite, you will note that the B.N. curve for the first eight feet of motion is the higher, and that at about eight feet the curves cross, the B.N. giving a final velocity of 2786 foot-seconds, or 500 feet below the cordite curve.

Then follows ballistite, which, with much lower initial pressure, gives a velocity of 2806 foot-seconds, or somewhat higher than that of B.N. Then follow three different sizes of cordite, the highest of which gives a muzzle velocity of 3284 foot-seconds, or a velocity nearly double that of the early R.L.G.

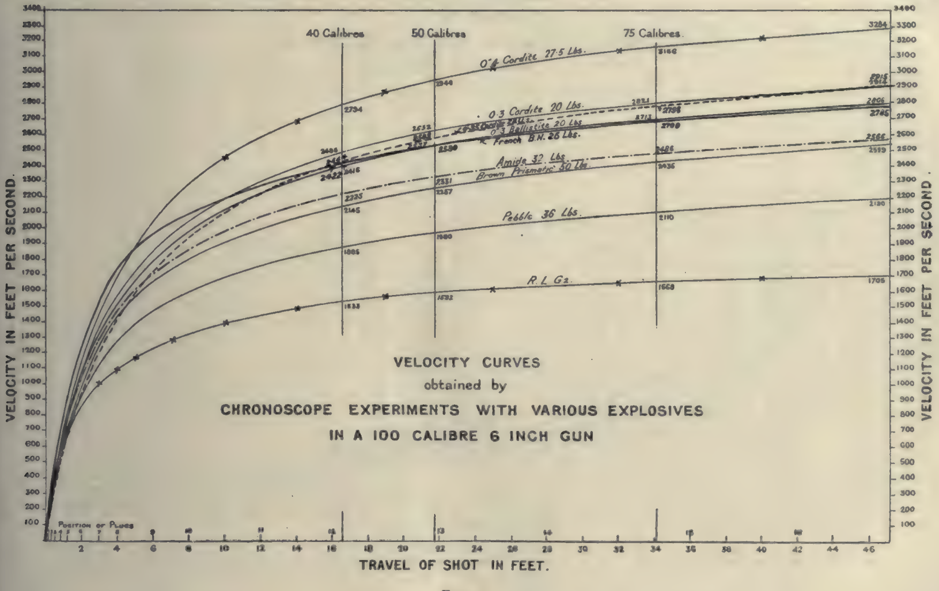

FIG. 2.

In the somewhat formidable-looking Table III. I have placed on the wall are exhibited the velocities and energies realised in a 6-inch gun with the various explosives I have named, and the Table, in addition, shows the velocities and energies in guns of the same calibre but of 40, 50 and 75 calibres in length, as well as in that of 100 calibres.

If you compare the results shown in the highest and lowest lines of this table, that is, the results given by the highest and lowest curves on the diagram, you will see that the velocity of the former is nearly twice as great as that of the latter, while its energy and capacity for penetration is nearly four times as great.

I need hardly remind most of you that in artillery matters it is the energy developed, not the velocity alone, that is of vital importance. I venture to insist upon this point, because so many of those who desire to instruct the authorities, write as if velocity were the only point to be considered. In a given gun with a given charge, if the weight of the shot, within reasonable limits, be made to vary, the ballistic advantage is greatly on the side of the heavier shot, and for three principal reasons.

(1) More energy is obtained from the explosive.

(2) Owing to the lower velocity the resistance of the air is greatly reduced.

(3) The heavier shot has greater capacity for overcoming the reduced resistance.

You will observe that on this velocity diagram, upon which I have kept you so long a time, is shown, not only the travel of the shot in feet, but the position of the plugs which gave the velocities. Further, on the higher and lower curves, the observed velocities are shown where it is possible to do so. Near the origin of motion the points are so close that is is not possible to insert them without confusing the diagram.

At the risk of fatiguing you, I show, in Fig. 3, curves showing the pressure existing in the bore at all points, these pressures being deduced from the curves of velocity.

You will note the point to which I drew your attention, with regard to the powder called B.N. You will remember that in the early stages of motion it gave velocity to the shot much more rapidly than did the other powders. You see the effect in the pressure curves, the maximum being considerably higher than any of the other pressures, while the pressure towards the muzzle is, on the other hand, considerably below the average.

I fear you may think I have kept you unnecessarily long with these somewhat dry details, but I have had reasons for so doing.

In the first place I desire to demonstrate to you the enormous advances which have been made in artillery by the introduction of the new explosives, and which we in a great measure owe to the distinguished chemists and physicists who have occupied themselves with these important questions.

Secondly, I desire to show you that the explosive which has been adopted by this country, and which we chiefly owe to the labours of Sir F. Abel and Prof. Dewar, is in ballistic effect inferior to none of its competitors. I might go further and say that it is decidedly superior.

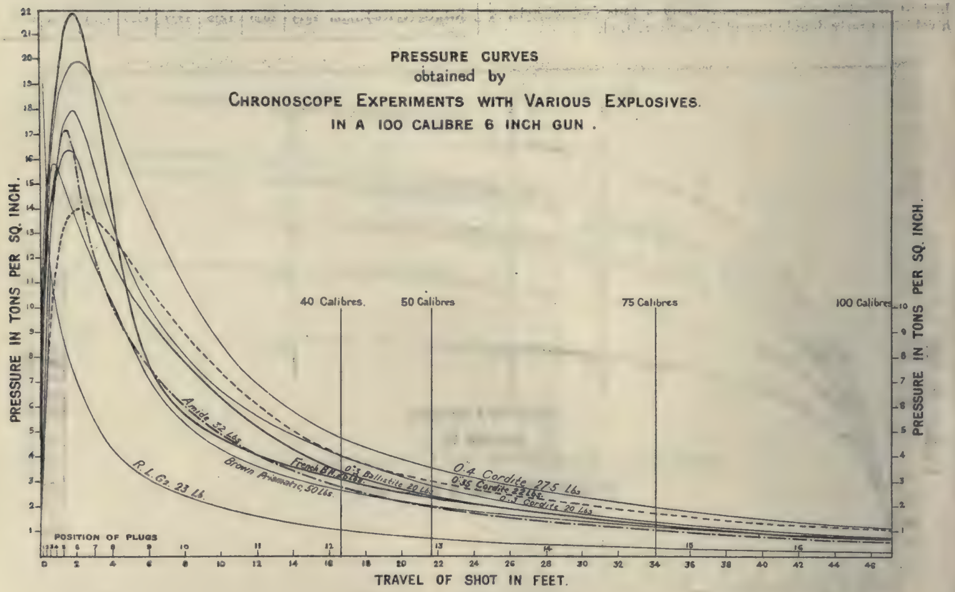

FIG. 3.

Lastly, at a time when the efficiency of all our arms, and especially our artillery, is a question which has been deeply agitating the country, I may do some good by pointing out that the authorities are well aware that any practicable velocity or energy they may desire for their guns is at their disposal.

They have such guns, I mean guns with high velocity and high energy—whether they have enough of them, and whether they are always in the right place, is another matter, for which perhaps the military authorities are not altogether responsible. But velocity and energy is not the only thing that is required under all circumstances in war, and I ask you to believe that if the War Office authorities have, for their field guns, fixed on a velocity very much below what is possible, they have had sound and sufficient reasons for so doing.

My firm and I, individually, have had much to do with the introduction of the larger high-velocity and quick-firing guns into our own and other services; but as an old artillery officer, in no way responsible for our field guns, I may perhaps be allowed to say that, whether as regards materiel or personnel, our field artillery is inferior to none anywhere; and I venture to add that in the present war it appears to have been handled in a way worthy of the reputation of the corps.

I fear the causes of some of our military failures at the commencement of the war must be looked for in other directions, and the present unfortunate war will turn out to be a blessing in disguise, if it should awaken the Empire to the necessity of correcting serious defects in our organisation, possibly the natural result of our constitution; and, in that case, the invaluable lives that have been lost will not have been sacrificed in vain.

(*To be continued.*)

## THE USE OF STEEL IN SHIPBUILDING.[1]

MANY changes and developments in the construction of ships for the mercantile marine have taken place during the last forty years. At the commencement of this period wood was still the principal material employed for shipbuilding, and although iron had been introduced for general shipbuilding purposes some twenty years earlier, the record of new tonnage added to the British Register in 1860 shows only about 30 per cent. to have been built of iron.

The general adoption of iron for shipbuilding on the Wear dates from about the year 1863, and by 1880 it had, in that district, entirely taken the place of wood. On the Clyde, Mersey and Tyne, iron shipbuilding was adopted at an even earlier date. So far back as 1855, iron had largely taken the place of wood for shipbuilding on the Clyde.

The difficulty of preventing the fouling of the bottoms of iron ships due to corrosion or marine growths, and the consequent loss of speed, led to various attempts being made to sheath the bottoms of iron ships and cover the wood sheathing with copper, yellow metal, or zinc sheets. The result was the introduction of the system of construction known as "Composite," in which the framing was of iron, with wood planking wrought on the iron frames, and sheathed with copper or yellow metal.

---

[1] Abstract of a paper read before the Institution of Naval Architects by Mr. B. Martell.

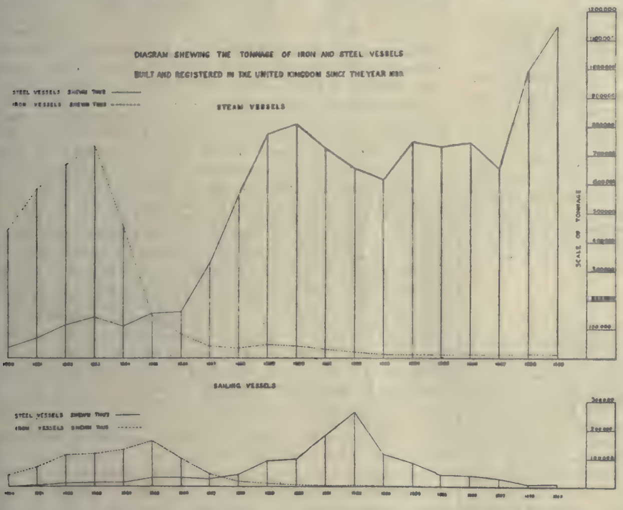
The early composite ships were classed as experimental, and subject to biennial survey, in order that the condition of the fastenings might be examined, and the effects of the galvanic action set up by the iron framing and yellow metal sheathing ascertained from time to time.

So far back as 1862, applications were made for vessels to be classed which were to be built with puddled steel, but in the absence of experience regarding the durability of steel, the Committee of Lloyd's Register felt it was not in their power to sanction the proposal.

In 1864, however, a steam yacht of 2400 tons was built for the Viceroy of Egypt under the survey of Lloyd's Register Surveyors, and constructed partly of steel. A reduction of about one-fourth was allowed in the steel scantlings from those required for an iron ship of the same size.

In April, 1876, Mr. James Riley, then manager of the Siemens Steel Works at Landore, read a paper before the Institution of Naval Architects on the production of mild steel, setting forth the results of experiments that had been made with steel manufactured by the Siemens-Martin or open hearth process, and showing the qualities of this material as to ductility and tensile strength.

These results were placed before the Committee of Lloyd's Register, and in 1877 plans from Messrs. J. Elder & Co. were approved for the construction of two paddle steamers to be built of this material for the English Channel service, with a reduction of about 20 per cent. in the scantlings which had been adopted for iron vessels.



In the same year, in consequence of a report which may be found in the volume of *Transactions* of this Institution for 1877, it was decided to admit steel with scantlings 20 per cent. lighter than prescribed for iron, in vessels building for classification, subject to the material having a tensile strength of from 26 to 30 tons per square inch, and an elongation of 20 per cent. on a length of eight inches. These limits of tensile strength have since been raised to 28–32 tons.

The progress in the use of mild steel for shipbuilding purposes may be judged from the fact that while in 1878 seven steel vessels, of 4470 tons, were classed in Lloyd's Register, and 435 iron vessels, of 517,692 tons, the record for the year 1885 showed 118 steel vessels, of 165,437 tons, as compared with 260 iron vessels, of 290,429 tons. As wood was superseded by iron as a material for shipbuilding, so in its turn iron has given place to steel. Of the total output of the United Kingdom during the past year, 98·8 per cent. of the tonnage was built of steel, and 1·1 per cent. of iron. The iron tonnage was principally made up of trawlers, and comprised no vessel of more than 303 tons.

The accompanying diagram shows the relative changes in the tonnage of steamers and sailing vessels of iron and steel built and registered in the United Kingdom since 1880.

Soon after the introduction of mild steel for shipbuilding purposes, attention was given to the making of heavy steel castings to take the place of iron forgings for stern frames, rudders, propeller brackets, stems, quadrant tillers, &c. These castings are required to be subjected to certain tests, and at the present time are often adopted in place of iron forgings.

It may be here remarked that, notwithstanding the early doubts as to the durability of steel, experience has shown that where proper care is taken to thoroughly clean and paint the surfaces, the deterioration is not appreciably greater than that of iron. In some parts, however, such as thin deck plating, and plating of inner bottom and floors under boilers, steel appears to be more liable to deteriorate, and in consequence of this, iron is often used for these parts in vessels otherwise constructed of steel.

## *UNIVERSITY AND EDUCATIONAL INTELLIGENCE.*

OXFORD.—An appointment will ere long be made to the new Wykeham professorship of physics, which will be endowed in accordance with statute by New College. It is understood that a portion of the space to be vacated in the University Museum by the removal of the Radcliffe Library will be utilised, at least temporarily, as a laboratory for the teaching of electricity.

Merton College proposes to contribute, out of its University Purposes Fund, the sum of 700*l.* towards the cost of fitting up, and 500*l.* towards that of maintaining for two years, the new electrical laboratory, provided that no further liability be hereby undertaken by the College. This proviso is intended to guard against the College University Purposes Fund being regarded as a permanent source of income. Messrs. W. Peterson, principal of McGill University, and John Fletcher, professor of Latin in the University of Toronto, have been appointed as representatives of the University at the centenary of the University of New Brunswick, and Mr. W. R. Morfill, reader in Russian, has been appointed representative at the five-hundredth anniversary of the University of Cracow.

The statute making the degrees of B.C.L. and D.C.L. accessible to persons who have obtained a degree in arts in other Universities, and study law in Oxford although they have not been admitted to the degree of B.A., has been approved by Congregation and Convocation; and also the decree instituting the new research degrees of Doctor of Letters and Doctor of Science.

It is proposed that the necessary qualification for intending candidates for the diploma in Geography shall be that candidates give satisfactory evidence that they have received a good general education, and not, as at first suggested, that they should have passed the examination for the B.A. degree.

On May 22 the honorary D.C.L. degree was conferred upon the following colonial representatives:—The Hon. Alfred Deakin, the Hon. James R. Dickson, C.M.G., and the Hon. Sir Philip O. Fysh, K.C.M.G.

The 212th meeting of the Oxford University Junior Scientific Club was held on Friday, May 11. Papers were read by Mr. S. A. Ionides, Balliol, on "Microphotography," and by Mr. P. Elford, St. John's, on "Chemists of the Nineteenth Century." The following papers will be read during the course of the present term:—"Musical Tetanus," Prof. Sir John Burdon Sanderson, F.R.S.; "The Labile Hydrogen Atom," Mr. A. F. Walden, New College; "A Method for Measuring the Diameter of the Earth," Rev. T. C. Porter.

CAMBRIDGE.—Dr. J. W. L. Glaisher, F.R.S., has been appointed by the council of the Senate a governor of St. Paul's School.

Sydney University, New South Wales, has been placed on the list of recognised schools of medicine.

The Rev. T. Wiltshire has founded a prize to be awarded annually for proficiency in geology and mineralogy. The prize is open to members of the University who have passed Part i. of the Natural Sciences Tripos, and are not of more than ten terms' standing.

Prof. J. Ward and Prof. R. Adamson, of Glasgow, are appointed electors to the Gerstenberg studentship in philosophy, open to students of natural science.

PROF. LEON GUIGNARD has been appointed director of the Paris School of Pharmacy.

PROF. LUDWIG BOLTZMANN, of Vienna, has accepted the invitation to the chair of physics in the University of Leipzig.

THE *Chemist and Druggist* announces that Prof. Moissan has been elected a member of the Paris Superior Council of Public Instruction, in succession to the late M. Planchon, deceased. He has also accepted the important post of professor of chemistry at the Paris Sorbonne, in place of M. Troost, who retires on account of advancing age.

## SCIENTIFIC SERIALS.

*American Journal of Science*, May.—Notes on [the geology of the Bermudas, by A. E. Verrill. The present Bermuda Islands are the remnant of a very much larger island, covering an area of about 300 to 400 square miles. A subsidence of at least 80 to 100 feet took place at a comparatively recent period. The Greater Bermuda, as well as the present Bermudas, are composed of shell sand drifted from the sandy flats by the winds in former times into hills, and afterwards consolidated by infiltration and exposure into what is known as Aeolian limestone. The shell sand is constantly increasing in amount, chiefly by the annual growth and death of small shells, as in former periods, so that the total mass of the islands is probably still increasing beneath the sea. The "red soil" of Bermuda is mainly the residue left after the destruction and solution of the limestones. The islands rest on the hidden summit of an ancient volcano. —Some boiling point curves, by C. L. Speyers. The author shows that the equation

$$\frac{n}{\mathrm{N}+n}=\frac{p-p'}{p}$$

accounts for the boiling point curves of every mixture for which the partial pressures of the constituents are known at some temperature not very far from the boiling point of the mixture under consideration.—Action of ammonium chloride upon natrolite, scolecite, prehnite and pectolite, by F. W. Clarke and G. Steiger. The authors show how the ammonium chloride reaction can be used for studying the chemical structure of these minerals, and that the orthosilicate formulæ for natrolite and scolecite must be discarded.—Siliceous calcites from the Bad Lands, Washington County, South Dakota, by S. L. Penfield and W. E. Ford. The calcites obtained from the new locality have a peculiar crystallisation, being steep hexagonal pyramids instead of rhombohedra.—Studies in the Cyperaceæ, by T. Holm. This paper deals with the segregates of *Carex filifolia*, Nutt.—Mineralogical notes, by A. F. Rogers. Describes various peculiar forms of gypsum and calcite. Twinned gypsum crystals from Lebo, Kansas, possess hemimorphic orthorhombic symmetry rather than monoclinic.—The Hayder Creek, Idaho, meteoric iron, by W. E. Hidden. This meteorite, weighing 870 grammes, was found at the bottom of a twelve-foot shaft. No companions have been found.—Explorations of the *Albatross* in the Pacific, by Alexander Agassiz. This is the author's fourth and last letter to the U.S. Fisheries Commissioner on the cruise of the *Albatross*. It describes the work in the Ellice, Gilbert and Marshall Islands, as well as the Carolines and Ladrones. The Truk Archipelago was perhaps the most interesting of the island groups of the Carolines, and it is the only group of the volcanic islands surrounded by an encircling reef which the author has seen in the Pacific, which at first glance lends any support to the theory of the formation of such island groups as Truk by subsidence. But a closer examination shows that this group is not an exception to the general rule thus far obtaining in all the island groups of the Pacific visited during this trip, that we must look to submarine erosion and to a multitude of local mechanical causes for our explanation of the formation of atolls and of barrier and encircling reefs, and that, on the contrary, subsidence has played no part in bringing about existing conditions of the atolls of the South and Central Pacific.

*American Journal of Mathematics*, vol. xxii. 2.—Remarks concerning the expansions of the hyperelliptic sigma-functions, by Oskar Bolza, are supplementary to two papers, by the same writer, in vol. xxi. pp. 107–125 and pp. 175–190.—On a certain class of groups of transformation in space of three dimensions, by H. F. Blichfeldt, is the carrying on of an investigation (by S. Lie) of groups of transformations in 3 variables, defined by the properties: two points have one, and only one, invariant; $s>2$ points have no invariants independent of such two-point invariants. This class belongs to a wider class in $n$ variables defined by the properties: not less than $m>1$ points may possess invariants, while $s$ points, $s>m$, may have no invariants independent of the $m$-point invariants. The wider class includes the group of Euclidean motions in space of 2 or 3 dimensions, the group of translations in space of $n$ dimensions, the group of Euclidean motions and similar transformations in space of 3 dimensions, &c. Certain groups are discussed and their general properties stated.—Dr. L. E. Dickson, in a paper on the canonical form of a linear homogeneous substitution in a Galois field, gives a short proof by induction of a result which M. Jordan had previously obtained by a rather lengthy analysis.—Dr. E. O. Lovett writes on families of transformations of straight lines into spheres. If a plane $\sigma$ containing two points $E$ and $E_1$ moves upon a coincident plane $\sigma_1$ containing two straight lines $g$ and $g_1$, so that $E$ remains upon $g$ and $E_1$ upon $g_1$, the two planes form a mechanism possessing the following well-known properties: Every point of $\sigma$ traces an ellipse upon $\sigma_1$, and every point of $\sigma_1$ traces a limaçon upon $\sigma$ (*cf.* Chasles, Aperçu, p. 49), a circle $c$ of radius $a$ in $\sigma$ rolls upon the inner side of a circle $c_1$ of radius $2a$ in $\sigma_1$. Every point of $c$ describes a straight line passing through the centre of $c_1$. Any two of these lines, with the points which generate them, can be taken for $g$, $g_1$ and $E$, $E_1$ in defining the movement. Mr. E. M. Blake's object, in his article on the Ellipsograph of Proclus, is to study (1) the curves generated by the points of $\sigma$ and $\sigma_1$; (2) the ruled surfaces generated by any straight line carried by $\sigma$ or $\sigma_1$ and not parallel to them; (3) the curves enveloped by any straight line of $\sigma$ or $\sigma_1$; (4) the developables enveloped by carried planes (*cf.* Cayley, on the kinematics of a plane, *Q.J.* xvi. 1878; Schell, "Theorie der Bewegung und Kräfte," i. pp. 227–230, and articles by Burmester).—Mr. N. J. Hatzidakis, in displacements depending on one, two, . . . $k$ parameters in a space of $n$ dimensions, extends to the general case results obtained for 4 dimensions by Prof. Craig (vol xx. 2) and M. Darboux.—The main object of Dr. G. A. Miller on the product of two substitutions is to prove the following theorem:—If $l$, $m$, $n$ are any three integers greater than unity, of which we call the greatest $k$, it is always possible to find three substitutions ($L$, $M$, $N$) of $k+2$ or some smaller number of elements, and of orders $l$, $m$, $n$ respectively, such that $LM=N$.

*Annalen der Physik*, No. 4.—Temperature and potential gradient in rarefied gases, by G. C. Schmidt. When a vacuum tube is heated, the positive light becomes stratified. The stratifications increase in breadth as the temperature increases. Eventually, the positive light retires towards the anode, so that the discharge becomes dark. At the kathode, on the other hand, an increase of the temperature produces an extension of the glow light, such as is produced by an increase of the current strength. When the dark discharge has set in, the potential gradient is greatest at the anode, and is proportional to the distance from the kathode.—Mechanical motions under the influence of kathode rays and Röntgen rays, by L. Graetz. Rotations similar to those produced by Quincke in liquids may be produced in air ionised by X-rays, by mounting light dielectric bodies provided with agate caps on needle points in the space between two condenser plates exposed to the rays. The sense of the rotation depends upon the initial tendency, except when the rotating body contains a metallic substance, in which case the direction of rotation depends upon the direction of the rays and the electric field. The rotations are explained by the electrostatic forces between the wall of the tube and the parts of the body charged by the ions. The author believes that these rotations furnish an explanation for the rotations under the influence of kathode rays first observed by Crookes.—Atomic and molecular magnetism, by S. Meyer. Special investigations of the magnetic susceptibilities of copper compounds have shown that there is no essential difference between cupric and cuprous compounds. Wherever the formation of a molecule out of its constituent atoms leads to a considerable contraction of volume, the molecular magnetism is increased, so that the result may even be a paramagnetic compound. Where, on the other hand, there is expansion, the diamagnetism increases.—Energy of kathode rays, by W. Cady. The author discusses the various methods of determining the energy of kathode rays. The thermopile and the bolometer have undoubted advantages as compared with the calorimeter, but it is necessary to know how much of the energy incident upon them is reflected, and how much energy is lost in the process of reflection. The author bases his calculations upon the supposition that 40 per cent. of the kathode energy is reflected, and that the amount of energy lost during reflection is 30 per cent.—Electric arc between metallic electrodes in nitrogen and hydrogen, by L. Arons. The electromotive forces necessary to produce an arc between metallic electrodes depends upon the nature of the surrounding gas. In air, silver electrodes give a fine arc, but no arc can be produced with them in nitrogen. Iron electrodes, which require a high voltage in air, require only a very low voltage in nitrogen.—Electrolytic records of electric currents, by P. Gruetzner. The author gives details of the method of recording alternating currents of high frequency with the aid of iodine paper, and shows that for low voltages it offers decided advantages over the dust-figure method.—Change of volume of rubidium during fusion, by M. Eckardt. The fusing point of rubidium is 37·80°. During melting, 1 gramme of rubidium expands by 0·01657 c.cm.

*Symons's Monthly Meteorological Magazine*, May.—Meteorological extremes: wind-force. This is the third of a valuable series of articles; the first two referred to pressure and temperature. The difficulties are far greater than in the other cases, as in determining wind-force observations no homogeneity exists either as regards the instruments employed, or the units of the various scales in which the results, either instrumental or estimated, are expressed. The instrument most generally used is Dr. Robinson's cup-anemometer, the few others being chiefly Osler's or Dine's pressure anemometers. In the velocity instruments the factor for obtaining the true velocity of the wind depends upon the length of the arms and the size of the cups. Until recently the factor used has been 3, but more recent experiments have shown that the speed at the cups should be multiplied by the factor 2·2, so that some very high velocities formerly recorded should be reduced by nearly one-third. Among the highest velocities recorded in this country (reduced by the new factor 2·2), we may mention a severe gale in the Irish Sea in January 1899, in which a rate of 90 miles per hour was recorded in one gust; the maximum mean force for an hour at Fleetwood was 75 miles. The highest recorded velocity in a gust was recorded by Dines's anemometer at Rousdon, in South Devon, in March 1897, viz. at a rate of 101 miles per hour. At Greenwich a pressure of 51½ lbs. on the square foot was recorded on January 18, 1881, which is equivalent to a velocity of about 130 miles per hour, but there is good reason for believing that in strong winds the records of these pressure plate anemometers are occasionally much too high. It is still a moot question, what is the strongest force that the wind attains, and whether the force in some of the gales which visit our exposed shores from the Atlantic is much exceeded in tropical cyclones.

*Bollettino della Società Sismologica Italiana*, vol. v. 1899–1900, No. 7.—List of earthquakes observed in the East, and especially in the Ottoman Empire, during the year 1896, by G. Agamennone. An extract from a paper noticed in NATURE, vol. lxi. p. 400.—The Etnean earthquake of May 14, 1898, by A. Riccò. The epicentre was at S. Maria di Licodia on the south-west slope of Etna, and the focus must have been shallow, for the shock was strong enough to damage many buildings near the centre of a small disturbed area.—Notices of earthquakes recorded in Italy (October 11–November 19, 1898), by A. Cancani; the most important being earthquakes in Sicily on November 1, 2 and 3, Dalmatia on November 8, the Ionian Sea on November 9, and distant earthquakes on October 12 and November 17.

No. 8.—The Modena-Bologna earthquake of the night of February 1–2, 1900, by G. Agamennone. A slight shock, with a disturbed area of about 60,000 sq. km., but recorded by a seismograph at Lubiana (330 km. from the epicentre).—On an electrothermic phenomenon in electrical contacts with slight pressure, by A. Cancani.—Latian earthquake of July 19, 1899, by A. Cancani, a paper noticed in NATURE, vol. lxi. p. 573.—Notices of earthquakes recorded in Italy (November 21–December 31, 1898), by A. Cancani, the most important being distant earthquakes on December 1 and 3.—On a new form of multiplication applicable to seismic movements and on a new seismoscope founded on the same, by G. Pericle.

*Bulletin de la Société des Naturalistes de Moscou*, 1899, No. 1.—Meteorological observations at Moscow in 1898, by E. Leyst.—On the development of green algues under conditions excluding the assimilation of carbon-dioxide, by Dr. A. Artari.—On the *Hedysarum* species (15) found in European Russia, Crimea and Caucasia, by B. Fedtschenko.—On the Hydrachnids of the neighbourhood of Moscow, by A. Croneberg (plate). Forty-nine species, several of which are new, are described.—On the iron-ores (*turjit*) of the South Urals, by J. Samoiloff. All these articles, with the exception of the last one, are in German, or contain German *résumés*.—Notes on Coleoptera of European Russia and Caucasia, by A. Semenoff.

*Memoirs of the Mathematical Section of the Novorossian (Odessa) Society of Naturalists*, vol. xix.—Foundations of a theory of analytical functions, by J. Timtchenko, continued from vols. xii. and xvi. This part contains the history of certain special questions, the discussion of which has mainly contributed to the development of the theory of these functions.

*Memoirs of the Kazan Society of Naturalists*, vols. xxxii. and xxxiii.—Materials relative to the flora of the northern boundaries of the black-earth region, by S. Griegorieff.—The corals of the Devonian deposits in the Urals, by N. Bojartsen (one plate). Fifty-six species are enumerated, several of these, as also one genus (*Nicholsonia*), being new.—On the saliva glands of *Periplaneta orientalis*, by A. Lebedeff (plate).—The Ranunculaceæ of Russian Turkestan, by Olga and Boris Fedtschenko. One hundred and fifty-eight species are enumerated, forty-three species being endemic, and thirty-eight species belonging to the Alpine region. A suggestion for the determination of the Turkestan species is given. All articles are summed up either in French or in German.

---

## SOCIETIES AND ACADEMIES.

### London.

**Royal Society**, May 10.—"On Certain Properties of the Alloys of Gold and Copper." By Prof. Sir W. C. Roberts-Austen, K.C.B., F.R.S., and T. Kirke Rose, D.Sc.

The alloys of gold and copper, which are of great industrial importance owing to their use in coinage, have not been subjected hitherto to systematic examination. It has been assumed that they differ widely from the silver-copper series, which has been studied from different points of view, but there is very little evidence on which this view can be based.

Examination with the aid of a thermo-couple and autographic recorder shows that the freezing-point curve of the gold-copper series consists of two branches setting out from the points of solidification of the pure metals and meeting at a point, which is the freezing point of the eutectic. The eutectic contains about 82 per cent. of gold and 18 per cent. of copper, or about 60 atoms of gold to 40 of copper, and solidifies at 905°. The general shape of the curve therefore resembles that of the silver-copper series when the abscissæ give the relative number of atoms.

Under the microscope, alloys containing more than 82 per cent. of gold show a minutely granular structure in which it is not certain that two constituents can be distinguished. The section of standard gold containing 91·6 per cent. of gold bears a close resemblance to that of standard silver prepared in the same way. The alloy with 80 per cent. of gold shows the characteristically-banded eutectic structure almost exclusively, and the alloys with less gold consist of crystals of copper set in a matrix of the eutectic.

Another point of similarity between the gold-copper and silver-copper series is that both the eutectics are brittle and show scarcely any extensibility; they differ in these respect from most other eutectics. Analysis of various portions of ingots of standard gold reveals the fact that liquation takes place as definitely as in standard silver, the difference in composition between the centre and the outside of similar ingots being, however, three or four times greater in standard silver than in standard gold. In the latter case, the centre contains from 0·3 to 1·0 part per 1000 less gold than the outside.

It follows from these results that the gold-copper series of alloys presents many points of similarity with the silver-copper series, and that the main difference is only one of degree, copper being apparently more soluble in gold in the solid state than in silver.

**Geological Society**, April 25.—J. J. H. Teall, F.R.S., President, in the chair.—The President read the following resolution which had been passed unanimously by the Council: "That this Council desire to place on record their deep sense of the loss which both science and literature have sustained in the death of the Duke of Argyll, who was the oldest surviving past-President of the Geological Society"; and stated that on behalf of the Council he proposed to communicate a copy of the resolution to the Duchess of Argyll, coupled with an expression of respectful sympathy.—On a complete skeleton of an Anomodont reptile from the Bunter Sandstone of Reichen, near Basel, giving new evidence of the relation of the Anomodontia to the Monotremata, by Prof. H. G. Seeley, F.R.S. The author discusses various views which have been expressed with regard to the position of the Labyrinthodonts. He has already separated these animals from the Amphibia and combined them with the Ichthyosauria in a group of reptiles named Cordylomorpha, and he enumerates a series of characters which constitute so close a link between the two types "that it is not possible, in the absence of evidence, to conceive of their being referred to different classes of animals." In conclusion, the author argues that the points of structure are so few in which Monotreme mammals make a closer approximation to the higher mammals than is seen in the fossil described and other Anomodontia, that the Monotreme resemblances to fossil reptiles become increased in importance. He believes that a group Theropsida might be made to include Monotremata and Anomodontia, the principal differences (other than those of the skull) being that Monotremes preserve the marsupial bones and the atlas vertebra. *Ornithorhynchus* shows pre-frontal and post-frontal bones, and has the malar arch formed as in Anomodonts and some other reptiles.—On Longmyndian Inliers at Old Radnor and Huntley (Gloucestershire), by Dr. Charles Callaway. The grits, with some associated slaty bands, forming a ridge near Old Radnor were considered by Sir Roderick Murchison to be May Hill Sandstone. The author has discovered that one of the beds of Woolhope Limestone, dipping westward, is crowded with rounded and angular fragments of grit bearing a general resemblance to the arenaceous parts of the Old Radnor Group.

May 9.—J. J. H. Teall, F.R.S., President, in the chair.—The Pliocene deposits of the East of England. Part ii.: The Crag of Essex (Waltonian), and its relation to that of Suffolk and Norfolk, by F. W. Harmer, with a report on the inorganic constituents of the Crag by Joseph Lomas. Three divisions of the Red Crag are proposed, namely, Waltonian, Newbournian and Butleyan, which are distinguished alike by the difference of their faunas, and by the position which they occupy. The first, with its southern shells, is confined to the county of Essex; the second, containing a smaller proportion of southern and extinct, and a larger proportion of northern and recent species, occupies the district between the Orwell and Deben, and a narrow belt of land to the east of the latter river; the third, in which Arctic forms such as *Cardium groenlandicum* are common, is found only farther north and east. All these beds are believed to have originated in shallow and land-locked bays, successively occupied by the Red Crag sea as it retreated northward, which were silted up, one after the other, with shelly sand. The conditions under which the Red Crag beds originated seem to exist at the present day in Holland, where sandy material brought down by rivers, with dead shells in great abundance from the adjacent sea, is being thrown against and upon the coast, principally by means of the westerly winds now prevalent. From meteorological considerations, it seems probable that strong gales from the east may have prevailed over the Crag area during the latter part of the Pliocene epoch.—A description of the Salt-Lake of Larnaca in the Island of Cyprus, by C. V. Bellamy. After a brief description of the general geology and geography of the island, the author proceeds to deal with the topography of the lake, which occurs in a basin shut off from the sea, its deepest part being about 10 feet below sea-level. The barrier between the salt-lake and the sea is made of stiff calcareous clay associated with masses of conglomerate resting on plastic clay, that on watery mud, and that again on stiff calcareous clay. The sea-water appears to percolate through the highest deposits, meeting with checks in the conglomerates, and thus reaches the basin somewhat slowly, where it is evaporated to dryness by the summer heat and deposits its salt. Artificial channels have been made, to carry the flood-water from the land direct to the sea, so that it does not dilute the brine of the lake. The rainfall in the catchment-area round the lake is at the most only enough to supply 223 million gallons, and as the lake contains 480 million gallons when full, the balance of 257 million gallons must be derived from the sea. The lake is probably situated on what was an extensive arm of the sea at the close of the Kainozoic era. The salt-harvest begins in August, at the zenith of summer heat, and it is reported that a single heavy shower at that time of year suffices to ruin it. Observations are given on the density of the water, the plants and animals in the water, and the lake-shore deposits.

**Zoological Society**, May 8.—Dr. W. T. Blanford, F.R.S., Vice-President, in the chair.—Mr. Sclater exhibited a mounted specimen of a male reedbuck, which had been obtained by Mr. Ewart S. Grogan on the Songwé River, north of Lake Nyasa. The specimen was of about the same size as the common reedbuck (*Cervicapra arundinum*), but differed from that species in several important points. Mr. Sclater considered it referable to a new species, and proposed to name it *Cervicapra thomasinae*.—Mr. C. Davies Sherborn made some remarks on the progress of his "Index Generum et Specierum Animalium," of which he expected the first portion (1751-1800), containing about 60,000 entries, to be ready for publication at the end of this year.—Mr. G. A. Boulenger, F.R.S., read a paper on the batrachians and reptiles collected by Mr. G. L. Bates in the Gaboon (French Congo), among which were specimens of ten new species and five new genera of the former, and of one new species of the latter, which were described. These descriptions were incorporated with a list of the previously known species from the Gaboon, by which it was shown that the batrachians known from this country reached thirty-nine in number and the reptiles eighty.—Mr. W. R. Ogilvie Grant read a paper on the birds of the Hainan, based on a collection sent home by the late Mr. John Whitehead from the Five-Finger Mountains in the interior of the island. Examples of many interesting species had been procured, which were either new to science or to the fauna of the island. Among the former, which numbered eleven, were mentioned a splendid silver pheasant, a remarkable night-heron, and a peculiar brown-and-white jay of the genus *Urocissa*. The paper contained a complete account of the avifauna of Hainan as known at the present time.—Mr. Philip Crowley read a paper on the Rhopalocera collected by the late Mr. John Whitehead on the Five-Finger Mountains in the interior of Hainan. Specimens of 108 species were contained in the collection, of which eight were described as new, and many others were recorded from that island for the first time.—Mr. J. S. Budgett read a paper, entitled "Some points in the anatomy of *Polypterus*," as deduced from an examination of specimens lately procured by the author in the River Gambia.—Mr. G. A. Boulenger gave a list of the fishes collected by Mr. J. S. Budgett during his recent expedition to the Gambia. Among these were examples of two new species, which were proposed to be named *Clarius budgetti* and *Synodontis ocellifer*. Altogether specimens of forty-two species of fishes were obtained by Mr. Budgett from the river.

**Mathematical Society**, May 10.—Prof. Elliott, F.R.S., Vice-President, in the chair.—The chairman having read the by-laws bearing upon the subject of the special meeting, announced that it was proposed "that by-law iv. 1, be amended by substituting the words 'half-past five o'clock in the afternoon' for 'eight o'clock in the evening.'" The motion having been seconded by Dr. J. Larmor, F.R.S., was carried unanimously.—At the ordinary meeting, Dr. Glaisher, F.R.S., communicated a congruence theorem relating to Eulerian numbers and other coefficients.—Prof. Lamb, F.R.S., spoke briefly on a peculiarity of the wave-system due to the free vibrations of a nucleus in an extended medium.—Prof. Love, F.R.S., gave a description of some diagrams illustrating a paper, by Mr. J. H. Michell, which treats of distributions of stress in two dimensions.—The following papers were communicated by their titles:—The differential equation whose solution is the ratio of two solutions of a linear differential equation, by Mr. M. W. J. Fry; Note on a quinquisectional equation, by Prof. L. J. Rogers; On the differentiation of single theta functions, by the Rev. M. M. U.

Wilkinson; and linear substitutions commutative with a given substitution, by Dr. L. E. Dickson.—Lieut.-Colonel Cunningham, R.E., V.P., showed that numbers which are expressible in the *two* forms $N=\frac{\mu x^2+\nu y^2}{\alpha}=\frac{\mu' x'^2+\nu' y'^2}{\alpha'}$ are always *composite*, when $\mu\nu=\mu'\nu'$; and showed how to reduce them to the forms $N=X^2+\mu\nu Y^2=X'^2+\mu\nu Y'^2$, the factorisation of which is known from Euler's researches.

**Royal Meteorological Society**, May 17.—Dr. C. Theodore Williams, President, in the chair.—A paper was read on the Wiltshire whirlwind of October 1, 1899, which had been prepared by the late Mr. G. J. Symons, F.R.S., a few days before he was stricken down with paralysis. This whirlwind occurred between 2 p.m. and 3 p.m., commencing near Middle Winterslow and travelling in a north-north-easterly direction. The length of the damage was nearly twenty miles, but the average breadth was only about 100 yards; in this narrow track, however, buildings were blown down, trees were uprooted, and objects were lifted and carried by the wind a considerable distance before they were deposited on the ground. Fortunately the greater part of the district over which the whirlwind passed was open Down, otherwise the damage and perhaps loss of life would have been considerable. At Old Lodge, Salisbury, the lifting power of the whirlwind was strikingly shown by several wooden buildings being lifted up and dropped down several feet north-west of their original position. At a place eighteen miles from its origin the whirlwind came upon a rick of oats, a considerable portion of which it carried right over the village of Ham and deposited in a field more than a mile and a half away.—A paper by Dr. Nils Ekholm, of Stockholm, was also read on the variations of the climate of the geological and historical past and their causes. In this the author attempts to apply the results of physical, astronomical and meteorological research in order to explain the secular changes of climate revealed by geology and history.

### Dublin.

**Royal Dublin Society**, February 21.—Prof. G. F. Fitzgerald, F.R.S., in the chair.—Prof. W. N. Hartley, F.R.S., communicated his papers on the action of heat on the absorption spectra and chemical constitution of saline solutions, and on the occurrence of cyanogen compounds in coal-gas, and of the spectrum of cyanogen in that of the oxy-coal-gas flame.—Prof. E. J. McWeeney gave an account of the recently demonstrated connection between mosquitoes and malaria, with a lantern demonstration of the life-history of the former.—Prof. T. Johnson communicated a note on Sclerotium disease of Jerusalem artichoke grown at Greystones, county of Wicklow.

March 21.—Dr. F. T. Trouton, F.R.S., in the chair.—Dr. G. H. Pethebridge read a paper, entitled "Contributions to the knowledge of the action of inorganic salts on the structure and development of plants."—Mr. R. J. Moss (in the absence of Dr. W. E. Adeney) communicated a paper, by Prof. E. A. Letts and Messrs. Blake, Caldwell and Hawthorne, on the nature and speed of the chemical changes which occur in mixtures of sewage and sea-water.—Prof. J. Joly read a paper on the theory of the order of formation of silicates in igneous rocks, which was illustrated by a diagram (see p. 84).

April 25.—Prof. J. Emerson Reynolds, F.R.S., in the chair.—Prof. J. Emerson Reynolds, F.R.S., read a paper on recent analyses of the Dublin gas supply, and observations thereon.—Prof. G. A. J. Cole communicated a paper by himself and Mr. J. A. Cunningham on certain rocks styled "felstones," occurring as dykes in the county of Donegal.

### Edinburgh.

**Royal Society**, May 7.—Sir Arthur Mitchell, K.C.B., in the chair.—Mr. John Aitken, F.R.S., read a paper on the dynamics of cyclones and anticyclones, Part ii., which was illustrated by an ingenious experiment showing the production of vortex columns in the air. Over the upper metal surface of a flat box through which steam was blown was spread a sheet of brown paper thoroughly soaked with hot water. A steady gentle blast of air was driven across this steaming surface by means of a rotating fan; and when a barrier was intercepted so as to cut off half of the surface from the direct effect of the blast, a succession of whirls was started at the boundary between the sheltered and unsheltered parts of the surface. These whirls were plainly visible in the columns of rotating cloud, and showed on a small scale some of the characteristics of cyclones. According to Mr. Aitken's mode of looking at the phenomenon, the blast of air produced by the fan is analogous to the anticyclonic marginal wind which is regarded as driving the cyclone. The relations between the upper and lower currents in a cyclonic movement were also illustrated in the experiment.—Mr. R. C. Punnett communicated a paper on certain Nemerteans from Singapore, in which several facts of morphological interest were brought to light, notably the presence, in one species, of ducts placing the anterior portion of the alimentary canal in communication with the excretory system, and so with the exterior; and the different features shown in the termination of the lateral nerve-cords in a single genus where there might be a commissure either above or below the rectum, or else no commissure at all.—Mr. R. T. Omond, in a paper on the reduction to sea-level of the Ben Nevis barometer, pointed out that, using the ordinary reduction formula, we get an appreciable difference between the observed sea-level pressure at Fort William and the reduced Ben Nevis reading. Leaving out of account all cases in which strong winds were blowing, Mr. Omond had worked out in detail the hourly readings for a period of time extending over six years, and gave reasons for his belief that the discrepancy noted above was due to a false estimate of the average temperature of the air between Fort William and Ben Nevis. This average was not the mean of the bottom and top temperatures.

**Mathematical Society**, May 11.—Mr. Muirhead, President, in the chair.—A theorem in continued fractions (Prof. Steggall), on certain elementary inequality theorems (Prof. Gibson), note sur un problème de géométrie (Mons. Ed. Collignon); communicated by Dr. Mackay.

### Paris.

**Academy of Sciences**, May 14.—M. Maurice Lévy in the chair.—On a zenitho-nadiral apparatus designed to measure the zenithal distances of stars near the zenith, by M. A. Cornu. In front of a horizontal telescope carrying a wire micrometer is placed a special arrangement of two mirrors making an angle with each other of 90°. Four images can be seen simultaneously, that of the star near the zenith, the cross wires, the reflection of these wires in the mercury bath, and the image of the wires from the special reflector. When the image of the movable wire coincides with its reflected image from the mercury bath, the nadiro-zenithal image of this wire passes through the zenith, whatever may be the deviation from a right angle of the angle between the mirrors. The arrangement possesses important advantages over the methods at present in use.—Remarks on a meteor which fell in Bolivia on November 20, 1899, by the French Chargé d'Affaires at La Paz.—On divergent series, by M. Le Roy.—On the representation of non-uniform functions, by M. L. Desaint.—On a modification which metallic surfaces undergo when submitted to light, by M. H. Buisson. Under the influence of light, the metallic surface changes its state as measured by the rate at which it loses a charge of electricity, this change not being permanent but gradually disappearing when the radiant energy is cut off.—On the thermoelectric properties of some alloys, by M. Émile Steinmann. The alloys studied were ten nickel steels, four samples of platino-iridium, three of aluminium bronze, five telegraphic bronzes, five brasses, and four of German silver, at temperatures ranging from 0° to 260° C. In the binary alloys the observed electromotive forces are arranged in the order of magnitude of one of the components, but no simple relation could be deduced between the electromotive force and chemical composition in the case of nickel steel or of ternary alloys.—Duplex and diplex transmission by electric waves, by M. Albert Turpain.—Experiments in wireless telegraphy from a free balloon, by MM. J. Vallot, J. Lecarme and L. Lecarme. It was found to be possible to transmit messages to the balloon without an earth wire, even up to a distance of six kilometres and a vertical height of 800 metres.—An arrangement designed to prevent the interception of despatches in wireless telegraphy, by M. D. Tommasi.—On the hydrated calcium peroxides, by M. de Forcrand. A thermochemical paper.—On the allotropic transformations of the alloys of iron and nickel, by M. L. Dumas.—Preparation of some aluminium compounds and of the corresponding hydrogen derivatives, by M. Fonzes-Diacon. Details are given of the preparation of aluminium sulphide, selenide, phosphide, arsenide and antimonide. By the decomposition of these substances the hydrides $H_2S$, $H_2Se$, $PH_3$ and $AsH_3$ are obtained in a very pure state. $SbH_3$ can also be prepared in considerable quantity.—The estimation of thallium, by M. V. Thomas. The oxidation of thallous to thallic salts is carried out with bromoauric acid, the precipitated gold being weighed. Provided that the quantity of thallium present is not too small, the results are very exact.—Action of anhydrous aluminium chloride upon acetylene, by M. E. Baud. The aluminium chloride absorbs nearly four times its weight of acetylene, hydrogen, marsh-gas and ethylenic hydrocarbons being evolved. Complicated condensation products are formed, which are being further examined.—Some new organometallic combinations of magnesium and their application to syntheses of alcohols and hydrocarbons, by M. V. Grignard (see p. 85).—Santalenes and santalols, by M. M. Guerbet. A description of the isolation of two alcohols and two hydrocarbons from essence of sandalwood, together with the products resulting from the action of acetic acid, hydrochloric acid, and nitrosyl chloride upon the hydrocarbons and acetic anhydride, and phos phorus pentoxide upon the alcohols.—On tyrosinase, by M. C. Gessard. Tyrosinase is a ferment isolated from fungi, it possessing oxidising powers, giving a red oxidation product with tyrosin.—On the oxidation of erythrite by the sorbose bacterium and production of a new sugar, erythrulose, by M. Gabriel Bertrand (see p. 85).—On the amount of iron in hæmoglobin from the horse, by MM. L Lapicque and H. Gilardoni.—On a method allowing of the extraction of the sugar from molasses by means of the ordinary boiling apparatus, by M. Paul Lecomte.—Chlorophyll assimilation in plants confined in rooms, by M. Ed. Griffon.—A new self-registering apparatus for continuous currents, by MM. Auguste and Louis Lumière.

### GÖTTINGEN.

**Royal Society of Sciences.**—The *Nachrichten* (mathematico-physical section), Part iii., for 1899, contains the following memoirs communicated to the Society:—

October 28, 1899.—E. Riecke: Lichtenberg figures in the interior of Röntgen tubes.—W. Voigt: on a problem of Kohlrausch's in thermodynamics.—P. Gordan: new proof of Hilbert's theorem on homogeneous functions.

November 25.—W. Kaufmann: outlines of an electrodynamical theory of gaseous discharges (Part i)..

December 14.—W. Kaufmann: the same (Part ii.).

December 9.—G. Bohlmann: a problem concerning the "smoothing-out" of statistical curves.

January 13, 1900.—S. Kantor: a theorem in determinants.—A. Schoenflies: a proposition in the analysis of position.—E. Neumann: on Robin's method for determining electrostatic potential.

February 8.—W. Voigt: remarks on the theory of so-called thermomagnetic effects.

February 3.—E. Zermelo: on the motion of a system of points in relation to inequations of condition.

February 17.—A. von Koenen: on the age of North German Wealden formation (*Wälderthon*).

### AMSTERDAM.

**Royal Academy of Sciences**, April 21.—Prof. H. G. Van de Sande Bakhuyzen in the chair.—The following papers were read:—Prof. Kluyver on approximation formulæ concerning the prime numbers, not exceeding a given limit. The author shows that it is possible to express the approximate value of the sum of the $(-s)$th powers of these prime numbers, if only their total number be given. A similar formula gives an approximation to the value of the logarithm of the least common multiple of all integers below a given number.—Prof. Winkler, on behalf of Mr. M. A. van Melle, on some reflexes in respiration in connection with Laborde's method of re-establishing respiration stopped by narcosis by rhythmically pulling the tongue.—Prof. Franchimont, on behalf of Dr. Greshoff, on Echinopsine, a new crystalline vegetable base. This communication was accompanied by remarks by Prof. Kobert, of Rostock, and Prof. Verschaffelt, of Amsterdam.—Prof. van Bemmelen, on behalf of Dr. F. A. H. Schreinemakers, on the composition of the vapour phase in the system of water and phenol with one and with two liquid phases.—Prof. Bakhuis Roozeboom, (*a*) on behalf of Dr. A. Smits, on decreases in vapour tension and rises of the boiling point in the case of diluted solutions; (*b*) on behalf of Dr. Ernst Cohen, on thermodynamics of Clark's normal element.—All the above papers will be inserted in the *Proceedings*.—The following papers were presented for publication in the *Proceedings*:—(*a*) One by Prof. Schoute, entitled "Joachimsthal Theorem for Normal Curves"; (*b*) one by Prof. Bakhuis Roozeboom, on behalf of Dr. Ernst Cohen, entitled "Studies on Inversion (I.)."

THURSDAY, MAY 31, 1900.

## *A LIFE OF SCHÖNBEIN.*

*Christian Friedrich Schönbein*, 1799–1868. *Ein Blatt zur Geschichte des* 19. *Jahrhunderts*. Von Georg W. A. Kahlbaum und Ed. Schaer. I. Theil. Pp. xix+230. (Leipzig: Johann Ambrosius Barth, 1900.)

THIS work forms the fourth part of the series of monographs on the history of chemistry being published under the editorship of Prof. Kahlbaum, of Bâle, whose qualifications for the task have already been made known to English men of science in the notices of two of his earlier volumes published recently in these columns.[1] The present instalment covers the period from the time of Schönbein's birth to the year 1849, and is divided into four sections, which comprise respectively the intervals 1799–1820, the "Wanderjahre" 1820–1828, the residence at Bâle from 1828 till the discovery of the passivity of iron towards the end of 1835, and the prosecution of the researches on the latter subject and on cognate electrical subjects from 1836 till 1849. There is a supplementary section dealing with Schönbein as a teacher and friend, which is by no means the least interesting part of the present volume. A perusal of the work will not only convince its readers that Schönbein was altogether a remarkable man as a thinker and experimenter, but that his personality and work could not have fallen for delineation and estimation into any better or more appreciative hands than those of Dr. Kahlbaum and his colleague.

The subject of the present biography was born at Metzingen, in Schwabia, on October 18, 1799. Passing over his boyhood, it appears that in his fourteenth year he made his first start in life as a pupil in the chemical and pharmaceutical factory of Metzger and Kaiser at Böblingen, so as to become a practical chemist. He suffered much at first from home-sickness, which, the authors tell us, is a purely German ailment:—

> "Das bittere Leid des Heimwehs, dieser ächt deutschen Krankheit, die Engländer und Franzosen haben kaum ein eigenes Wort dafür, &c."

After seven years in this factory, he went, in 1820, into Dr. J. G. Dingler's factory for chemical products at Augsburg, on which occasion it is noteworthy that he underwent his only examination, and obtained his only certificate from Dr. Kielmeyer, of Stuttgart. The original document, which has been obtained by Dr. Kahlbaum, testifies that at that time Schönbein was possessed of a good scientific and practical knowledge of chemistry. Dr. Dingler's letter, setting forth the qualifications which he expected on the part of the young man whom he was thinking of engaging, is dated March 20, 1820, and as a revelation of the state of affairs in a German establishment during the early part of the nineteenth century, it will repay careful perusal. The chemist required by him was to have scientific rather than ordinary routine chemical knowledge; he was to have at the same time something more than a superficial acquaintance with chemistry, in order that he might be able to carry out the analytical work required of him; he was to have a knowledge of languages, so as to be able to translate, at least from French; he was to be possessed of moral rectitude, and to be entirely worthy of confidence. He was to come on probation for fourteen days, and if not found suitable he was to be sent back "carriage paid" ("bei Vergütung der Reisekosten"). If found suitable, he was to be boarded and lodged, and to receive from 200 to 300 florins per annum, with an increase to follow.

As the editor points out, Schönbein must have made good use of his time at Böblingen, since he seems to have come up to Dingler's requirements, and was appointed to the Augsburg factory; but before entering upon his duties he drew a fatal conscription number, and had to undergo a short term of military service. It appears, however, that he was soon discharged from this duty, through the intervention of the King, and in May 1820 he was "militärfrei."

The eight years from 1820–28 must have been years of great activity in Schönbein's early life. He remained only a few months at Augsburg, and then travelled from one University to another. His name is associated during this period with the Universities of Tübingen and Erlangen. While studying at the latter place, where he had Liebig for a contemporary, he was also holding the appointment of director in Adam's factory at Hemhofen, but finding that his factory work interfered with the prosecution of a regular course of study at the University, Mr. Adam relieved him of this work, and assisted him pecuniarily by appointing him tutor in his family.

Among many other interesting episodes in Schönbein's career at this period is his sojourn in England, which appears to have been the outcome of a taste for pedagogy inspired by his friend Christian Friedrich Wurm, who subsequently became professor of history in the Hamburg gymnasium—a man of many parts, a master of the English language and an ardent disciple of Pestalozzi, whose works he had translated into English. It was in 1826 that the young Schönbein entered the service of Dr. Mayo, who kept a school at Epsom, where Wurm was already engaged, for the purpose of imparting instruction in mathematics and natural philosophy on Pestalozzian principles in return for "50*l.* sterling per annum; with board, lodging and washing." The description of Dr. Mayo's establishment given by Wurm, and the criticisms which he makes upon the English educational methods of that time, are preserved in a letter to Schönbein written from Epsom in 1825, and published by Dr. Kahlbaum in the present volume. The editor comes to the conclusion that the Epsom academy was as far removed from the ideal Fröbel institute as the classical establishment of Dr. Blimbers at Brighton, in which young Paul Dombey was "forced" to death. Schönbein appears, however, to have made the best of his opportunities while in England, and to have paid visits to London and to Scotland, making friends and acquaintances, and gleaning knowledge wherever he went. In 1827 he left for Paris, and a long extract from his diary of travel, reprinted in the present work, is full of most interesting comparisons of English with French modes of travelling, and of the personal characteristics of the two nations. While Anglophobia, judging from some of the correspondence received by Schönbein at that time, appears even then to have existed in Germany, it is satisfactory to learn that he was never influenced by it :—

---

[1] NATURE, February 8, p. 337; and March 29, p. 513.

> "Dann war gerade ihm der afflammende Strohfeuerenthusiasmus der Franzosen nicht sympathisch, sein deftiges, bedachtes Wesen war sehr wohl, wir haben das ja gesehen, begeisterungsfähig und hingebend, aber, wie sein Humor nichts von dem sprühenden Feuerwerk französischen Esprits hatte, so wenig trat sein Enthusiasmus als schnell verrauschende Schwärmerei auf. Die langsame niedersächsische Art der Engländer war ihm, dem Schwaben, darum viel herzwärmender als das griechische Feuer der Franzosen."

It is, in fact, quite remarkable to find throughout this biography how warmly Schönbein felt himself in sympathy with England and English people. Faraday, Grove and Graham were his intimate and life-long friends. He appears to have gone to Paris under the same conditions and for the same purpose that he came here—to acquire a more intimate knowledge of the language, and to gain some insight into French pedagogy. The school in Paris, kept by a M. Rivail, in which he temporarily became a teacher, was unsatisfactory from every point of view, and on the whole the young German seems to have had anything but a pleasant time in the French capital about that period. But there, as elsewhere, he made the best of his opportunities by attending lectures at the Sorbonne, where he came under the influence of Gay-Lussac and Thénard, Biot, Dumas, Pouillet, Brongniart, &c., and by the time he returned to England to stay with his friend and Epsom colleague, Barron, at Stanmore, his appreciation of France and the French had considerably increased. Schönbein's views on the nature and constitution of Polytechnics, and his letters to Wurm written from Paris, and giving his experience of the Sorbonne and its professors, are full of interest.

In 1827, Merian, the professor of physics and chemistry at Bâle, was taken ill, and a substitute had to be found to carry on his duties. The post was first offered to Schönbein's friend, Engelhart, then also in Paris, who was unable to accept it, and afterwards to Schönbein, who was in England, and who finally undertook the duties, thus severing himself from this country, apparently to his regret, and becoming attached, in 1828, to that University, on which he ultimately shed such lustre. The first years of his connection with Bâle were unsettled by the provisional character of his appointment, and were further troubled by political disturbances, during which Schönbein himself bore arms, and it was not till February 1832 that he made his first communication to the scientific society of that town. This paper dealt with the classification of the elements into metals and non-metals, the former being defined as those elements which form basic oxides, and the latter those which form acid oxides. A few other papers followed during the years 1833–1835; one on the Pepys gas-holder, one on polarised light, one on an *ignis fatuus* observed at Bärenthal in the Black Forest, and one on the isomerism of chemical compounds. With the clearing of the political atmosphere and the cessation of hostilities, the University of Bâle underwent reorganisation, and Schönbein was appointed ordinary professor of physics and chemistry in 1834. His marriage took place the following year, towards the end of which (December 23, 1835) he made known to the "Naturforschenden Gesellschaft" his memorable work on the behaviour of tin and iron towards nitric acid, later communications on the passive state of iron and other metals having been made on January 21 and March 3, 1836.

The observation which formed the starting-point of Schönbein's researches appears to have been made by many previous investigators, among whom our own countryman, James Keir, F.R.S. (*Phil. Trans.* 1794) is given the priority. The period covered by the next section of the present work, viz. from 1836 to 1849, was full of activity and productiveness on the part of Schönbein, whose development of ideas, from his first experiments on the "passive" state of metals through all their ramifications into the various fields of electro-chemistry, is followed out and set forth by Dr. Kahlbaum with a masterly hand. As we are at this period well within what might be called the public aspect of Schönbein's work, when his results were being continuously published and discussed throughout the scientific world, it is unnecessary to dwell at any greater length upon the contents of the present instalment of his biography. It will interest English readers particularly to find how skilfully the authors trace the influence of Schönbein's correspondents, and particularly Faraday, upon his work. This work centred round the subjects of the origin of the electric current and the polarisation of the electrodes. The great controversy between the "chemical" and the "contact" theories of electromotive force was then raging, and it is now a matter of history how ably and staunchly Schönbein advocated the former. Most clearly are his views expressed in the extracts from his correspondence with Faraday, Poggendorff, Grove, De la Rive and others which the authors have brought together in this biography. Now and again passages occur which are really prophetic, such, for example, as his statement concerning the possible utility of the "Voltaic cell" in organic chemical investigation,[1] and his remarks[2] on the desirability of there being a more frequent blending of physics and chemistry in the same individual, as exemplified by Berzelius, Gay-Lussac, De la Rive, Becquerel, Daniel and Grove. Dr. Kahlbaum points to the modern school of physical chemistry as the embodiment of this wish.

In the concluding section, Schönbein's position in the world of science, as deduced from his own statements, is most instructively summed up. He was something more than a "physicist" or "chemist" :—

> "Also Schönbein war nichts weniger als ein kritikloser Anhänger der Naturphilosophie im gewöhnlichen Sinne des Wortes, als der er im allgemeinen verschrieen ist, aber er war eine durch and durch philosophisch angelegte Natur mit gefülltem philosophischem Schulsack und gut geschultem Denken, die eben immer aus theoretischen Ansichten heraus ihre Arbeiten unternahm."

This judgment is borne out by an extract relating to his work on ozone contained in a letter written to Liebig in 1866, in which he states that, although the detection of a peculiar smell in electrolytic oxygen was accidental, all that has since proceeded from this observation cannot be ascribed to accident.

---

[1] *Pogg. Ann.* 1839, xlvii. 583.

[2] *Beiträge zur physikalischen Chemie*, 1844.

Among the many interesting aspects of Schönbein's life and work dealt with in this section is his dislike for organic chemistry already referred to in his correspondence with Faraday. Dr. Kahlbaum, we may add, endorses this opinion with some very strong remarks of his own (pp. 204-205), which will, no doubt, be forgiven by the "Herren Organiker" in view of the very important service to the history of nineteenth century science which he is rendering by these biographical contributions. Then, again, one cannot but be struck by the versatility of Schönbein's genius as revealed by the narration of his connection with journalism. That the illustrious Bâle professor was possessed of great literary power is made clear by his biographer. It is worthy of record that Schönbein attended the Birmingham meeting of the British Association in 1839, and the Cambridge and Southampton meetings in 1845 and 1846; of the first of these he gave an account in his "Reisetagebuch eines deutschen Naturforschers," of which extracts in English were published in the *Athenæum*. As an excellent example of his literary style may be mentioned the charming description of Easter festivities in Germany, written in English to Faraday in 1856. With respect to the literary style and method of publishing his scientific writings, there is a long and interesting critical letter from De la Rive in 1839, in which he reproaches Schönbein for being too diffuse, for writing too much and at too great a length, for introducing too often unverified suppositions, and, in fact, as we should say at the present time, for transferring the contents of his laboratory notebooks to the pages of his published memoirs:—

> "C'est une voie tentative, à la tête de laquelle est Faraday dans ce moment, qui publie, publie le journal de ses expériences, aussi voyez le peu d'effet que font ses travaux sur le continent."

This criticism, by the way, is endorsed by Dr. Kahlbaum, who regrets that the Germans, "on account of its foreign origin," should have imitated a style which he characterises as incivility (Unhöflichkeit) to the readers.

Enough has been gleaned from this volume to show our readers that as a contribution to the history of the science of the nineteenth century, it is in no way inferior to its predecessors.

## PROFESSOR TAIT'S SCIENTIFIC PAPERS.

*Scientific Papers.* By Peter Guthrie Tait, M.A., Sec. R.S.E. Vol. ii. Pp. xiv + 500. (Cambridge: At the University Press, 1900.)

PROF. TAIT is to be congratulated on the energy with which this reprint is being pushed forward. The first volume, noticed in NATURE, vol. lx. p. 98, is already followed by a second, so that the completion of the work at an early date may be anticipated.

The present instalment contains two considerable experimental investigations; one of these, on the compressibility of water at very high pressures, was suggested by a previous research on the *Challenger* thermometers; for the second, on impact, we are indebted to the author's well-known interest in golf. There is also a very interesting discussion of the cause of the "soaring" flight of a golf ball.

The most important theoretical research consists of a revision of the kinetic theory of gases, from the old standpoint of elastic spheres. All students of this intricate subject will be glad to have Prof. Tait's acute examination of it in the present compact form. It is interesting to note, by the way, the author's frank confession: "I have . . . . abstained from reading the details of any investigation (be its author who he may) which seemed to me to be unnecessarily complex. Such a course has, inevitably, certain disadvantages, but its manifest advantages far outweigh them!" Let us hope that no indolent reader will be tempted to turn against Prof. Tait himself a *dictum* which conveys a very salutary warning to authors!

One of the most useful features of this reprint is the number of short papers which to many readers will now become known for the first time. There are also included a few biographical notices, as well as articles from the "Encyclopædia Britannica." In a note to the article on "quaternions" we are told that the sketch of the subject recently given by Prof. Klein in the "Theorie des Kreisels" rests on a misapprehension. This is one disappointment the more for those students who have vainly striven time after time to get a clear notion of what a quaternion really is, and who hoped that they had found at last something like a clear and compact and intelligible account of the matter. If, in spite of the fact that "the grandest characteristic of quaternions is their transparent intelligibility," men like Cayley and Klein are declared to have gone astray, one may be excused for asking whether there may not be something wanting after all in the official presentations of the subject?

The paper on the laws of motion hardly addresses itself to points on which a modern reader would seek enlightenment. Instead, we have verbal questions as to the meaning of "force" and the proper translation of certain phrases of Newton. Are not such questions disposed of once for all by the simple statement that since the time of Newton scientific people have specialised their usage of the word "force"? Although this has not been an unmixed advantage, it is probably now irrevocable. Still, one may reasonably urge that it is hardly fair to take a popular term, used in a great variety of senses, to attribute it for special purposes one and only one of these, and then to denounce as ignorant any one who continues to use it in its former latitude. The scorn, for example, which has been called forth by the term "centrifugal force" has often been most unjust, the physical notions of the users being clear enough, although they were not expressed in the conventional phraseology. The endless discussions which have been inflicted on us as to the meaning of the word "weight," furnish another instance of the trouble which may be wrought by specialists attempting to usurp functions which do not properly belong to them.

The last paper in the volume, on the teaching of natural philosophy, contains matter which probably hardly any one would question. Yet it well deserves reprinting, if only for the passage near the end which speaks of "the fatal objections to the school-teaching of physical science," based on the intrinsic difficulties of the subject, and the maturity of mind required to overcome them. Any one who is aware of the futility and the pedantry of a good deal that goes on in schools under the name of science-teaching will thank Prof. Tait for this courageous utterance. The mischief is that school-teaching is dominated by examinations, and that the kind of science-teaching which it is possible, and highly desirable, to have in schools does not readily lend itself to examination-tests of the ordinary kind.

The volume is marked by the same beauty and accuracy of printing as the former one. It is intimated that a third volume will complete the work.

HORACE LAMB.

## WYATT'S BRITISH BIRDS.

*British Birds; with some Notes in reference to their Plumage.* By C. W. Wyatt. Coloured Illustrations. (London: William Wesley and Son, 1899.)

WHETHER the beautifully illustrated work on the same subject by the late Lord Lilford leaves room for the present volume and its predecessor, is a question for the publisher rather than for the reviewer to answer; but, if the stream of books on the subject be any criterion, the appetite of the British public for natural histories of the avifauna of their own country seems insatiable. Apart from all this, the present work, of which the first volume was issued in 1897, has high claims on the consideration of the public, the large size (4to.) of the paper on which they are printed permitting the plates to be on a scale of greater magnitude than in the work above-mentioned, while their excellence from an artistic point of view, as well as their apparent fidelity to nature, leaves little or nothing to be desired from the point of view of the connoisseur in animal painting. In too many instances we have either an inartistic but truthful portrait of the creature depicted, or an artistic picture in which details of coloration are sacrificed to the general effect; but in the present case, the happy mean appears to have been attained in these respects. The plates are signed with the initials "C. W. W.," but we are told in the preface that the colouring has been done by the daughters of Dr. Bowdler Sharpe, whose training is a sufficient guarantee for its accuracy.

It must, indeed, be understood that the book stands or falls by the plates, as the letterpress is restricted in the main to details concerning the plumage of the specimens figured, or to generalities relating to seasonal changes of colour, nothing in the way of description being given.

When the scientific names applied to the different species are those of almost universal acceptation, no references to other works are added; but in the case of those where uniformity is by no means general, a reference is made to the synonyms used in standard manuals, such as the fourth edition of "Yarrell." It may be added that the reference to the latter work in the case of the Hen-Harrier appears to have been introduced by mistake, as the nomenclature employed is the same. As regards generic nomenclature, the author adopts a middle course, avoiding the inordinate "splitting" followed by some ornithologists, as he does the excessive "lumping" favoured by others.

The first volume was devoted to the resident Passeres of the British Islands, and as the present commences with the migratory members of the same order, it will be evident that the author does not confine himself to a strictly systematic arrangement. In excluding the casual visitors, which, in our own opinion, have no right whatever to the title of British Birds, the author differs from the plan followed by some of his brother ornithologists, whose object seems to be to draw up as long a list as possible, without any regard to the facts of geographical distribution. The other groups included in this volume include the Picarians, Owls, Hawks, and Pigeons, so that the Game Birds, Waders, and Water-Birds alone remain for its successor.

As a handsome, and at the same time an accurate, series of volumes for the drawing-table, the work may be heartily commended to all bird-lovers with whom "money is no object."

R. L.

## OUR BOOK SHELF.

*Our Native [American] Birds, how to protect them, and attract them to our homes.* By D. Lange. Pp. x + 162. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1899.)

LEST our readers should be misled into thinking that the present little volume is but another item in the already large literature of British ornithology, we have ventured to indicate its birth-place by a bracketed interpolation in the title.

The author, to whom the love of birds is evidently second nature, starts with the assertion that, with the exception of a few counties, the number of song-birds has of late years been steadily decreasing in the United States, and then proceeds to consider in detail—firstly, how this unfortunate state of things has been brought about, and, secondly, how it may best be remedied. Nor are song-birds alone considered, a certain amount of space being devoted to game-birds (inclusive of the *Anatidae*), many of which have likewise suffered severely.

The fact of the decrease in the former group seems to rest on conclusive evidence; the main causes assigned being lack of suitable nesting-places, want of water and food, the abundance of cats (domestic and feral), the ravages committed by boys, collectors, and plume-hunters, the aggressive habits of the English sparrow, and the use of poison in gardens and farms.

As regards legislative protection, the author wisely leaves this to the various "Audubon Societies," which have been established in the States, and other suitable agencies; devoting his attention mainly how to supply to his feathered friends such objects as are essential to their well-being, and how to guard them from the attacks of their chief foes. As our readers are aware, many towns and villages in the States are located on the open prairie, where the absence of cover renders the birds especially liable to destruction; while even in districts more favoured by nature there seems to be a great tendency to make the gardens of residents as open and bare of shrubbery as possible. Old hollow trees, too, which form the nesting-places of so many species, have likewise been ruthlessly felled, so that the unhappy birds have literally no retreats wherein to hide.

Accordingly, the planting of trees, vines and shrubs (especially kinds which afford good cover and edible berries) is strongly urged, while beds of suitable kinds of flowers, such as gladioli, should be planted to attract humming-birds. For species building in hollow trees, nesting-boxes should be provided in suitable sites; while drinking and bathing vessels should be furnished in the dry season, and abundance of suitable food at all times. The noxious sparrow is to be hustled out of the usurped nesting-places, while coils of barbed wire, or suitable wire fences, must be used to balk prowling cats. As to the best means of dealing with the human foes of birds, these, as already said, are mainly left to the powers that be; but the formation of "bird-leagues," by members of the female sex who are willing to forego the ornamentation of their head-gear by the plumes of songsters, is strongly urged, as is the repression of the ordinary collector. Education, and the establishment of an annual "bird-day," are also regarded as important factors in the scheme.

The author has performed his task in a manner calculated to interest his readers, and his work should be acceptable to those on both sides of the Atlantic who love to hear bird-music around their homes. R. L.

*Der Ursprung der Kultur.* Von L. Frobenius. Bd. i. Der Ursprung der Afrikanischen Kulturen. Mit 26 Karten, 9 Tafeln, sowie ca. 240 Text illustrationen. Pp. xxxi + 368. (Berlin: Gebrüder Borntraeger, 1898.)

THIS is the first volume of an ambitious work. The author proposes to seek out the Origin of Civilisation on what he considers to be a new plan. But in reality Mr. Frobenius can only work on the old lines; he can only compare one custom with another, and use the same old weak argument from analogy to prove connection between tribes who have similar customs: "er lehrt alte Weisheit als neue." ("Programm": p. xii.). He proclaims the virtues of his "new plan," however, in the very manner of the Teutonic *Gelehrte*: he considers himself to be laying the foundations of a new science (p. xiv.): "Was bedeuten alle Entbehrung und Entsagung, wenn sie auch noch so herb sein mögen, gegenüber dem grossen Glücke, schaffend und Schöpferisch bei der Gründung einer Wissenschaft teilnehmen zu können. Ich habe die bitteren Stunden und herben Übel nie so stark empfunden, wie die Freude über die Erfolge, *das stolze Gefühl des selbstständigen Schöpfers.* Und ich habe den herzlichen Wunsch, dass etwas von jener Spannkraft, die Müdigkeit und alle sonst vielleicht verzeihlichen und berechtigten Wünsche vergessen lässt, aus diesen Blättern dem Leser bemerkbar werden und in ihn übergehen möge." The italics are our own: we greatly fear that Mr. Frobenius, like so many of his "Fachgenossen," has no sense of humour. He does not forget to castigate his predecessors in ethnological study, some of whom are apparently prone to set fool's caps on their heads and give them out to be academical costume (p. ix.). The whole "Programm" which precedes the book is a typical product of what the author himself calls the "überhitzten Gelehrtenkopf" (p. ix.).

Apart from the rather ridiculous pretensions of its introduction, the book as a whole is useful enough as a series of essays on various phases of African ethnology, which are often very interesting, *e.g.* the chapter on building-styles (p. 194 ff.). They cannot, however, be said to prove much with regard to the origin of African civilisation, which is presumably what they are intended to do. The author's arguments in favour of his theory of the "Malayonigritish" origin of West African culture are interestingly put forward.

Absolutely nothing whatever is said about *Ancient* Africa: not a word with regard to the Zimbabye ruins, which we had expected to find exhaustively discussed here: not a word about the wonderful civilisation of Egypt, with the earliest beginnings of which we have now, thanks to the energy of Prof. Petrie and Messrs. Quibell, De Morgan and Amélineau, been brought into close contact, and which appears more and more African in character the further we go back. Not a single comparison of the Zulu and Egyptian head-rests even, to take the instance which first comes to mind; but a curious misapprehension on p. 97, where Fig. 60 is described as a "Sceptermesser der Pharaonen," whatever that may be: the object in question is merely the well-known and commonly-used Egyptian sword called *Khepesh* (on account of its resemblance to the shape of an animal's *thigh*, e.g. *khepesh*), which had nothing in particular to do with either Pharaohs or sceptres.

Of the illustrations, while the majority are good, some are certainly very bad, *e.g.* Plate iv. and Figs. 137, 139.

*The Amateur's Practical Garden Book.* ("The Garden Craft Series.") By C. E. Hunn and L. H. Bailey. Pp. vi + 250. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1900.)

THE sub-title of this book very aptly indicates the nature of its contents, "The simplest directions for the growing of the commonest things about the house and garden."

The subjects dealt with are arranged alphabetically, beginning with Abobra and ending with Zinnia. It must not, however, be concluded that the book is merely a dictionary of plant names. It is much more.

Thus, under the heading "Annuals," we have an explanation of the term, the cultural details necessary for their proper growth, together with lists classified according to the colour of the flower, or the purpose the flowers have to serve.

The book is written for the climate of New York, but with the requisite modifications it is suitable for gardeners in this country also. It is severely practical, and principles, though perceptibly diffused, are not so much as mentioned.

*Man and his Ancestor: a Study in Evolution.* By Charles Morris. Pp. 238. (New York: The Macmillan Company. London: Macmillan and Co., Ltd., 1900.)

THE author has written this little book for the purpose of providing the intelligent person with a good and sufficient reason for the evolutionary faith that is in him. It is true that there is no book of a non-technical nature that quite covers the ground taken by the author, and it is only fair to him to state that he has filled this gap in a most creditable manner. It is obvious that many stages in the evolutionary history of man can only be guessed at by us, and that there is much room for discussion in these hypotheses as well as in the interpretation of accepted facts; but Mr. Morris is not aggressively dogmatic, nor has he striven to be sensational. There are, however, several statements to which exception can be taken in the chapter on the "Vestiges of Man's Ancestry." If Mr. Morris thinks the function of the thyroid is a "minor and obscure one," let him have his own excised and then he will know. Club foot is not generally regarded as a reversion to the anthropoid foot. Taking it all round, the book may be safely recommended to that class of readers for whom it was intended, and it may lead such to consult the recognised works on the various topics on which he touches. Owing to no references being given, inquirers will have to seek elsewhere for an introduction to the literature of human evolution. The author has not considered his little book worthy of an index.

*A First Geometry Book.* By J. G. Hamilton and F. Kettle. Pp. ii + 91. (London: Edward Arnold, 1900.)

THIS little book contains a series of elementary exercises in geometry based on the method of allowing the pupil to deduce as many principles as possible after, and from the results of, experiments or exercises dependent on them. The deductions are drawn from the pupil's own measurements of his drawings to scale of the usual geometrical figures. From this it will be understood that the book really consists of a series of graduated exercises which appear to be well chosen and arranged, and likely to prove suggestive to teachers and useful to students beginning their first studies of the subject.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### A Third Specimen of the Extinct "Dromaius ater," Vieillot; found in the R. Zoological Museum, Florence.

IN January 1803, a French scientific expedition, under Baudin, visited the coast of South Australia and explored Kangaroo Island, called by them "Isle Decrès." One of the naturalists attached to the expedition was the well-known F. Péron, who wrote an interesting narrative thereof. He noticed that Decrès Island was uninhabited by man, but, although poor in water, was rich in kangaroos and emus (*Casoars* he calls the latter), which in troops came down to the shore at sunset to drink sea-water. *Three* of these emus were caught alive, and safely reached Paris; we learn from the "Archives du Muséum" that one was placed in the Jardin des Plantes, and two were sent to "La Malmaison," then the residence of the Empress Josephine. We learn later that two of these birds lived to 1822, when one was mounted entire and placed in the ornithological galleries of the "Muséum," the other was prepared as a skeleton and placed in the comparative anatomy collections. No mention is made of the ultimate fate of the third specimen.

Péron was unaware that the emu he had found on the Kangaroo Island was peculiar and specifically quite distinct from the New Holland bird; this was found out much later, and *too late*; for after Péron and his colleagues no naturalist evermore set eyes on the pigmy emu of Kangaroo Island in its wild condition! It appears that when South Australia was first colonised, a settler squatted on Kangaroo Island and systematically exterminated the small emu and the kangaroos. When the interesting fact was ascertained that Péron's emu was a very distinct species quite peculiar to Kangaroo Island and found nowhere else, *Dromaius ater* had ceased to exist; and the only known specimens preserved in *any* museum were the *two* mentioned above, in Paris.

For some years past my attention had been drawn to a small skeleton of a Ratitæ in the old didactic collection of the R. Zoological Museum under my direction; it was labelled "Casoario," but was in many ways different from a cassowary; but other work kept me from the proposed closer investigation, and it was only quite recently, during a visit of the Hon. Walter Rothschild, on his telling me that he was working out the cassowaries, that I remembered the enigmatical skeleton. A better inspection showed us that it is, without the least doubt, a specimen of the lost *Dromaius ater*. I afterwards ascertained that it had been first catalogued in this museum in 1833; that most of the bones bore written on them in a bold round hand, very characteristic of the first quarter of the nineteenth century, the words "Casoar mâle;" and lastly, that during the latter part of Cuvier's life, about 1825-30, an exchange of specimens had taken place between the Paris and the Florence Museums. I have thus very little doubt that our specimen is the missing *third* one brought alive to Paris by Péron in 1804-5.

This highly interesting ornithological relic is now on loan at the Tring Museum, and can be seen there by any ornithologist in England who may wish to examine it. I intend shortly to give a fuller notice of this valuable specimen.

HENRY H. GIGLIOLI.

R. Zoological Museum, Florence, May 15.

### Chlorophyll a Sensitiser.

IT was with a feeling of great satisfaction that I read the concluding lines of Dr. H. Brown's highly interesting presidential address (NATURE, September 14, 1899), I was glad to see that this distinguished chemist, to whom the physiology of plants is so much indebted, adopts certain views on the chlorophyll function, which I have been defending for more than a quarter of a century against the leading authorities of the German Physiological School (Sachs and Pfeffer). But since some slight errors seem to have crept into Dr. Brown's statements of my opinions on the subject, I may, perhaps, be allowed to bring forward the following corrections.

Dr. Brown seems to believe that the analogy between the action of chlorophyll and that of a chromatic sensitiser was "first pointed out by Captain Abney" and "more fully elaborated" by me; and secondly, that I give "a far too simple explanation of the facts" by admitting a "*mere physical* transference of vibrations of the right period from the absorbing chlorophyll to the reacting carbon dioxide and water."

To begin with the less important question of priority, I must confess that up to this date I am not aware of Captain Abney's claims. Had I known them, I should have been the first to acknowledge my debt to that accomplished investigator, whose brilliant achievements in this line of research I have never omitted to admire. The fact that the dissociation of the carbon dioxide in the green leaf is affected by the rays of light absorbed by chlorophyll was for the first time established by my researches in 1873, and an account of these experiments presented to the International Congress of Botany in Florence (May 1874).[1] At the same date (1873) Prof. H. Vogel made his important discovery of the chromatic sensitisers, and in November 1875, E. Becquerel applied it to the chlorophyll-collodion plates. In May 1875 appeared my Russian work on the chlorophyll function, of which the French article[2] in the *Annales de Chimie et de Physique* of 1875, as expressly stated, is but an extract. In this French translation the idea that chlorophyll may be considered as a sensitiser is fully discussed. Consequently any claim of priority may be fairly advanced, only in favour of a paper having appeared in the short interval of a year—from May 1874, when I *announced the fact*, to May 1875, when I *interpreted it* in the light of H. Vogel's recent discovery. On consulting the *R. S. Catalogue of Scientific Papers*, I could not find any paper of Captain Abney's for this period 1874-1875.[3]

So far concerning the priority question. Passing to the second point, I am sorry to say Dr. Brown is decidedly in the wrong, for in my French paper just cited, and which probably escaped his notice, after discussing the quite recent discoveries of H. Vogel and Edmond Becquerel, I conclude: "Ou ne saurait pour le moment décider la question de savoir si cet effet serait dû uniquement à un phénomène physique, ou bien si la matière colorante prendrait part à la transformation chimique. Cette dernière manière de voir ferait rentrer l'action de cette matière (chlorophylle) dans la règle générale de l'action accélératrice des matières organiques dans les réactions photochimiques, car c'est généralement en absorbant les produits de la dissociation, effectué par la lumière, que les substances organiques détruisent cet equilibre qui tend à s'établir entre le corps décomposé et les produits de décomposition et c'est ainsi qu'une dissociation partielle aboutit à une décomposition complaite."[4] At a later date, in a report presented to the International Congress of Botany in St. Petersburg (1884), taking in account the subsequent photographical work on the sensitisers, I brought forward experimental proof that chlorophyll may be considered a sensitiser in Captain Abney's sense of the word: "La chlorophylle est un sensibilisateur régénéré à mesure qu'il se décompose et qui provoque en éprouvant une décomposition partielle la décomposition de l'acide carbonique."[5]

From all these quotations it may be inferred that I always kept in view the chemical aspect of the chlorophyll function, now advocated with such stress by Dr. Brown.[6]

But I did not content myself with such purely theoretical considerations, and ever since have been in search of what Dr.

---

[1] *Atti del Congresso Botanico tenuto in Firenze*, 1875, p. 108. At a still earlier date (*Botanische Zeitung*, 1869, No. 14), I found out the source of T. W. Draper's error, and proved that the process is chiefly due to the red rays of light.

[2] "Recherches sur la décomposition de l'acide carbonique dans le spectre solaire par les parties vertes des végétaux" (Extrait d'un ouvrage "Sur l'assimilation de la lumière par les végétaux," St. Petersbourg, 1875, publié en langue Russe) *Annales de Chimie et de Physique*, 5 serie, t. xii. 1877.

[3] Prof. Pfeffer, in his account of the whole subject ("Pflanzenphysiologie." Zweite Auflage, pp. 325-341), goes so far as to attribute this sensitiser theory of the chlorophyll function to Prof. Reinke, whose paper appeared ten years later.

[4] *L.c.* p. 40. In a footnote I add that certain physiological facts seem to agree with this point of view.

[5] "État actuel de nos connaissances sur la fonction chlorophyllienne" (*Annales des Sciences Naturelles Botanique*, 1885, p. 119).

[6] At a still earlier date (in a Russian work on the "Spectrum Analysis of Chlorophyll," St. Petersburg, 1871) I even expressed Dr. Brown's present point of view in the form of an equation:

$$\begin{array}{l} \mathrm{XO+CO_2=XCO+O_2} \\ \qquad\qquad\quad \underline{\mathrm{+H_2O}\qquad\quad} \\ \qquad\qquad\quad \mathrm{=XO+CH_2O+O_2} \end{array}$$

X being Dr. Brown's hypothetical "reduced constituent of chlorophyll.'

Brown so appropriately terms the "reduced constituent of chlorophyll." My persistent endeavours resulted in the discovery of *protophylline*, a substance obtainable through the action of nascent hydrogen on chlorophyll solutions.[1] Some years later I discovered this substance in the living plant.[2]

The existence of a *reduced constituent of chlorophyll* may be consequently considered as a perfectly established fact, and will be probably brought to account by the chemical theory of the chlorophyll function. I conclude my French paper with the following words:—" L'étude de ces substances ne manquera pas à jetter une vive lumière sur le *coté chimique* de la fonction chlorophillienne *qui à été étudié dans ce dernier temps presque exclusivement au point de vue physique*."

To sum up: though it may be clearly seen that for nearly thirty years I have been considering chlorophyll as a *chemical* sensitiser (or, strictly speaking, an *absorbent* of the products of dissociation of $CO_2$ and $H_2O$), still even now I must confess that this theory lacks direct experimental proof and may be considered only as a matter for further research, whereas the physical aspect of the question (*i.e.* that $CO_2$ and $H_2O$ are decomposed through the agency of those rays of the spectrum, which are absorbed and somehow transformed by chlorophyll) is but the expression of a fact, put beyond any doubt by my researches, both on the decomposition of $CO_2$ and on the production of starch in the living plant.[3] But I do not abandon the hope that the discovery of the *protophylline* may turn out some day to be a step in the direction of a *chemical theory* of the chlorophyll function, somewhat similar to that of the colouring matter of the blood—an analogy which has been present to my mind ever since I became acquainted with the classical researches of Sir G. G. Stokes in that direction.

University, Moscow. CLEMENT TIMIRIAZEFF.

---

I REGRET that M. Timiriazeff should regard the concluding lines of my presidential address as doing him some injustice.

No one can be more impressed than I have been with the extreme beauty and importance of M. Timiriazeff's work, which cleared away many illusions, and for the first time prominently brought out the fact that the rays corresponding to the principal absorption band of the chlorophyll spectrum are those which are mainly active in the assimilatory process.

I have always regarded M. Timiriazeff's paper of 1885 (*Ann. des Sciences Nat.* [*Bot.*], vol. ii. p. 99) as being one of the most convincing and eloquent expositions in scientific literature, and the final proof of the proposition there laid down was given by the author in 1890 (*Compt. rend.* 110, 1346), when he succeeded in showing that the reappearance of starch in a depleted leaf exposed to a pure spectrum only takes place in the region of the red corresponding exactly to the principal absorption band of chlorophyll.

With regard to the first point raised in M. Timiriazeff's letter, I may say that when preparing my address I experienced a difficulty in ascertaining who it was that first drew attention to the existing analogy between chlorophyll and a chromatic sensitiser.

There is no complete list of Sir William Abney's papers, and knowing that he has sent many communications on this and cognate subjects to photographic journals in various parts of the world, I applied to Sir William Abney before writing what I did. There can be no doubt that chromatic sensitisers were very much "in the air" immediately after Vogel's discoveries of 1873, and it is probable that the application of these new ideas to chlorophyll occurred independently to Abney, Timiriazeff and Becquerel.

M. Timiriazeff's second objection is that I have not sufficiently taken into account his views of the function of chlorophyll as a *chemical sensitiser*. On this point I may say that I had in view his paper of 1885: "État actuel de nos connaissances sur la fonction chlorophyllienne," which it was fair to imagine fully embodied the author's view up to that date. It is certainly the *physical rôle* of chlorophyll which is there insisted upon, as the following quotation indicates: "Le rôle de la chlorophylle dans le phénomène de la décomposition de l'acide carbonique peut donc être résumé ainsi: elle absorbe les radiations qui possédent la plus grande énergie et transmet cette énergie aux molécules de l'acide carbonique qui, à elles seules, n'éprouveraient pas de décomposition, étant transparentes pour ces radiations énergiques."

That the physical conception was certainly uppermost in M. Timiriazeff's mind at that time is further shown by the diagram and remarks immediately following, in which he regards the molecules of carbon dioxide as suffering "shipwreck" in the luminous undulations corresponding to maximum amplitude.

It is, however, quite clear from M. Timiriazeff's references to his paper of 1877, and especially to his Russian paper of 1871, neither of which I have seen, that he has expressed views which are practically identical with those contained in the concluding remarks of my address. It is to be regretted that these ideas were not again clearly brought forward in the 1885 paper, which purported to give the author's latest views on the whole question, and that the physical idea of the immediate transference of the energy of radiation was there made the dominant one.

52, Nevern Square, Kensington. HORACE T. BROWN.

### A Simple Experiment on Thermal Radiation.

THE following experiment, which has been successfully performed by our students for several years, may be of interest to teachers of physics.

Three chemical thermometers are chosen of equal size and shape. The bulb of one is silvered, of the other covered with dead black paint by dipping it into a mixture of lamp-black and alcohol, whilst the third is left unchanged. For silvering, any of the well-known solutions and processes will be applicable. The thermometers indicate the same temperature if there is no source of radiation near them.

But if a gas flame, for example, an Argand burner, be placed at a distance of 20 centimetres from them, so that the thermometers, hanging from a stand, are at equal distances from the flame, the temperature rises at a different rate, and to a different, though in each thermometer constant, height. The silvered thermometer gives the lowest reading, and the blackened the highest, whilst the thread of the uncovered one stops at some point between these readings nearer to that of the blackened than the silvered; for the different surfaces of the thermometers absorb the radiation of heat generated in the flame in different proportion. The blackened thermometer bulb almost completely absorbs the rays falling on it; the silvered and polished bulb reflects the radiation reaching it; the plain glass bulb partly reflects and partly absorbs the rays. Thus, none but the silvered bulb thermometer indicates the temperature of the air communicating heat to it by conduction. As the other thermometers rise in temperature, they emit radiation; and when the amount of heat emitted from them equals the amount received through radiation from the gas flame, they are in the final stationary state, which is, of course, reached by the thermometers at different temperatures.

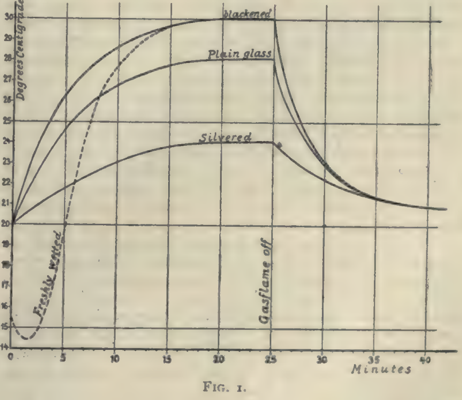

FIG. 1.

If the gas flame is put out, the temperatures of the three thermometers fall at different rates. Observations made simultaneously on them every minute, and plotted on squared paper, illustrate fairly well Kirchhoff's law enunciating that a body emits those rays best which it absorbs best. When the gas flame is replaced by a freezing mixture, the greatest fall of temperature is experienced by the blackened thermometer, and the least by the silvered one, for the same reasons.

---

[1] The first description of this curious substance was given in two short notes communicated to these columns: "Colourless Chlorophyll" (NATURE, 1885, p. 342) and "Chlorophyll" (NATURE, 1886, p. 52). For more ample details, see *Comptes rendus*, 1889.

[2] "La protophylline dans la plante vivante" (*Comptes rendus*, 1889).

[3] "Enregistrement photographique de la fonction chlorophyllienne par la plante vivante" (*Comptes rendus*, 1884).

The same arrangement of thermometers may be used to show the cold produced by evaporation. For this purpose, the bulb to be blackened has to be wetted immediately before starting the radiation experiment. First the temperature of this thermometer falls, even though the gas flame be lighted, but after a few minutes its temperature rises very quickly to reach the same state of equilibrium as when taken with dry black paint. In Fig. 1 the dotted curve represents the behaviour of the freshly wetted blackened thermometer.

For silvering the thermometer bulbs, we use most successfully the process described first by A. Martin in *Poggendorff's Annalen* (cxx. 1863, p. 335), and reprinted in many of the books on practical physics. K. T. FISCHER.

München (Bavaria), Kgl. Technische Hochschule.

## THE TOTAL ECLIPSE OF THE SUN.

THE last total solar eclipse of this century appears to have been successfully observed all along the line of totality. The weather conditions were favourable at all the observing stations, and numerous photographic and visual observations have been made of the phenomena revealed during a total eclipse. Elaborate arrangements were made to study the eclipse in all its aspects, and it has fortunately been possible to carry them out in a most satisfactory manner.

A code telegram received at the Solar Physics Observatory, South Kensington, from Sir Norman Lockyer, states:—"At the time of the eclipse the weather was excellent, and all the instruments were satisfactorily employed. There was a fall in temperature during the eclipse of from 4° to 6° C. The eclipse was not a dark one, and very few stars were seen. The corona exhibited large equatorial extensions and distinct polar tracery as expected. Observations of the shadow band were fully made in two planes. In the fixing up of the instruments, and the making of the observations, assistance was given by about 150 of the officers and crew of H.M.S. *Theseus*, which conveyed the eclipse party from Gibraltar to Santa Pola, a few miles south-west of Alicante."

The corona was similar to those observed during the eclipses of 1878 and 1889—both epochs of sunspot minimum—and thus supplies additional support to the probability of a real connection between the coronal structure and the state of solar activity. There were two long equatorial streamers, the western one being bifurcated and extending about two solar diameters. Several observers note that the inner corona was visible for at least *five* seconds after totality.

The eclipse was a short, and therefore a bright, one, which accounts for the general report that no shadow was seen either on land or in the atmosphere, and that very few stars were visible. Mercury and Venus were, however, observed. All the reports agree in estimating the duration of totality as shorter than was expected, so that the lunar tables will need slight revision for future computations.

Important observations were made of the shadow bands, which are stated to be very different in many respects from those previously observed. From one of the American stations it is reported that the bands were about one inch in breadth, their general direction being south 56½° E.; before totality their motion was at right angles to this—that is, almost north-east; and in the opposite direction after totality. Superposed on the linear bands, however, were certain dark patches previously unnoticed, having a motion at right angles to that of the bands. Baily's beads were well seen at the instants of second and third contact.

Prof. Todd, at Tripoli, is reported to have successfully employed twenty photographic cameras, one of which was furnished with a lens of 24 inches aperture.

The party at Pinehurst, from the U.S. Naval Observatory, under Prof. Skinner, obtained a good series of spectrum photographs, including five with plane and concave gratings and four with an objective prism; also five large scale photographs of the corona with a lens of forty feet focus.

Prof. Pickering obtained a good series of photographs with the new large instrument he had specially made for searching for an intra-Mercurial planet.

As we go to press, the following description of the observing parties at Santa Pola has been received from Sir Norman Lockyer.

### PREPARATIONS AT SANTA POLA.

*Santa Pola, Friday, May* 25.

The party from the Solar Physics Observatory arrived here on May 17, and now, thanks to the assistance so freely rendered by the Spanish authorities of all grades, and the strong working parties furnished by H.M.S. *Theseus*, the instruments are all in order and we are ready for the eclipse.

At Gibraltar the Captain of the *Theseus* sent off Mr. Daniels, torpedo gunner, to meet the Expedition, and the sixty-nine cases of instruments were carefully transferred to a lighter, and so soon as they were landed here those belonging to each instrument were at once brought alongside the piers which had already been erected for them on a site as near the landing stage as possible, thanks to the diligence of Mr. Howard Payn, a volunteer assistant who had preceded the party by rail and had secured the necessary bricks at Alicante.

The prismatic cameras, and those of the ordinary kind, fed by cœlostats and siderostats, with all prisms and mirrors, were in adjustment by the 21st, and drills were begun on the 22nd.

The parties of observers are as follows; and careful notes of the arrangements made are being kept, as some improvements have been made on those adopted in 1898.

*Parties on Shore.*—Prismatic cameras. (1) One prism (20 ft.); (2) two prisms (7 ft. 6 in.). Coronagraphs. (3) Graham (f. 6·5); (4) Dallmeyer (f. 8·0 about); (5) De la Rue (f. 17·5); (6) long focus (f. 48). (7) Discs. (8) Shadow bands. (9) Meteorology. (10) Stars. (11) Landscape colours.

*Parties on Board.*—(1) Stars. (2) Shadow. (3) Meteorology. (4) Landscape.

The whole party is in robust health, thanks to the glorious climate and any amount of work in the open air. We live in a little inn, which since the Queen's birthday has blossomed into the "Victoria Hotel," kept by one Frasquito Dols, a Spanish sailor and sea-cook, a regular "handy man," who has put up mosquito curtains, and rigged up a lift to carry our well-cooked food and excellent local wine to the first floor where we reside; in rooms which, though furnished with unparalleled simplicity, are absolutely clean. It seems a pity that more do not know of this delightful climate so near home, in which the winter months may be so pleasantly spent in the shadow of date palms.

The ship is much further away from the shore than in 1898—some 2000 yards—and the winds rise very suddenly in the open roadstead. The administration of the camp, therefore, devolves upon Lieut. Doughty, R.N., who, with Lieuts. Andrews and Patrick, remain constantly on shore in a pile-dwelling—a bathing establishment which has seen better days, and has been rechristened "Theseus Villa."

The "Scotch Commission," as it is called here—that is, Dr. Copeland's party—has chosen a site up the hill behind the town some distance from the jetty.

Elaborate arrangements have been made for the observation of shadow bands, two walls, E. and W. and N. and S., composed of first-class volley targets 16 × 6 ft., having been erected on a level space which has been whitewashed.

Six discs have been set up on spars, and most careful drills have taken place. I have been quite astonished at the exact reproduction of all the features of a dummy corona set up on each occasion.

It appears that the east wind is the best for us, and it is blowing now; a cloudy morning generally is followed by a cloudless sky in the afternoon. The weather chances are good, but they are not perfect.

NORMAN LOCKYER.

## *FIFTY YEARS OF GEOLOGICAL SURVEY IN INDIA.*

THOUGH the Honourable East India Company had showed their interest in the advancement of geological science by the appointment, so long ago as 1818, of a geologist to the Great Trigonometrical Survey, it is but fifty years since the first "Report of the Geological Survey of India for 1848–49," by Dr. John McClelland, was published. In 1851 Dr. McClelland was relieved by Dr. Thos. Oldham, who, on his arrival in Calcutta, found the Geological Survey represented in the capital of India by a room, a box and a messenger. One assistant, Mr. W. Theobald, was already in the employment of the Company, and during the following five years seven assistants were appointed, of whom but Mr. H. B. Medlicott and Dr. W. T. Blanford, names cut deep in the record of Indian geology, survive.

It was not, however, till 1856 that the Geological Survey was established as a regularly organised service, with a sanctioned establishment of superintendent (now styled director), fifteen graded assistants and a palæontologist. In spite of the increased area over which British rule extends, the establishment sanctioned in 1856 remained the same, with some minor, temporary changes, and an alteration of nomenclature, till 1892, when, instead of an increase, the permanent staff was reduced by three, and to compensate for this reduction arrangements were made for the employment of two "specialists" for terms of years, who were expected to devote their services more especially to economic geology. From one cause and another, this scheme has not received a full trial yet, and it is only during the present year that the full sanctioned staff is at work. The experiments so far made in the temporary employment of assistance to the Geological Survey, for the special purpose of economic work, cannot be regarded as successful, and the result of the present trial will be watched with interest, as it is likely to have great influence in the shaping of the future course and policy of the Survey.

The concrete results of less than half a century's work with this inadequate staff are a geological map of nearly the whole of India proper, which is accurate as regards its main features for this large area, and as regards details for a large proportion of it; and a considerable acquaintance, largely accompanied by maps, with the mountainous country to the north-west and north, and of the countries to the east, which are included in the Indian Empire. The published results are contained in thirty volumes of the "Records," twenty-nine of the "Memoirs," and twenty volumes, not counting those only partly published, of the "Palæontologia Indica."

Besides this collection of separate memoirs there was prepared, with the approval and sanction of the Government of India, a "Manual of the Geology of India," in two volumes, by Messrs. H. B. Medlicott and W. T. Blanford, published in 1879, to which were subsequently added a volume on the "Economic Geology," by the late Dr. Valentine Ball, and one on the "Mineralogy," by Mr. F. R. Mallet. These volumes contained not only much information collected by the Survey, which it had not been possible to publish previously, but for the first time, by collecting scattered information into one general review, made the geology of India generally accessible and intelligible. The need for, and value of, these volumes is shown by the fact that they soon went out of print, and in 1894 a revised version of the first two volumes was issued. The progress of the Survey in the period intervening between these two issues had been so great that a totally different scheme could be adopted, and instead of the series of separate descriptions of isolated areas, which was to a large extent inevitable in 1879, it was possible to treat the geology of India as an harmonious whole in 1894. A re-issue of the third volume of the original edition, the volume on "Economic Geology," has also been commenced, but though nominally a re-issue, it is, even more than in the case of the stratigraphical and structural geology, a new book, being different in scope and in aims, and containing no part of the original work.

The results of the Geological Survey, apart from its publications, are to be looked for both in India and out of it. In India, in the economic development of the Empire; and out of India, in the influence they have had on the advancement of geological science. The former of these is naturally that to which the Administration attaches the greater importance, and in this connection the existence of the Survey is amply justified in the fact that two of the coal-fields, which yield an important part of the coal-supply of India, were discovered and explored by the Geological Survey. Singarenni, surveyed by Dr. W. King, and Umaria, by Mr. T. W. Hughes, have, from their geographical position, a much greater importance than would appear merely from a numerical statement of the number of tons of coal raised in them, for they serve to supply a large area with cheap fuel which would otherwise be deprived of that advantage. These two fields in themselves would justify the existence of the Survey, from an economic point of view, apart from other benefits; but besides this the existence of a band of trained advisers, and of the observations accumulated by them, has frequently been instrumental in preventing the useless expenditure of large sums of money, and in this way alone the Survey has rendered an ample return for its maintenance.

Though the Administration is naturally most interested in the economic aspects of the work of the Geological Survey, there has never been any attempt to convert it into a mere prospecting or mining department. The Government of India has always recognised purely scientific work as an important duty of the Survey, and regarded the advancement of science not only as a thing to be desired and encouraged on its own account, but as furthering and rendering more valuable the economic results of the Survey, by improving the instrument with which it works. It is this portion of the work of the Survey which is of the greater interest outside India, and more especially to the readers of NATURE.

First among the results which have influenced the course of geological science may be placed the recognition of the importance of deposits formed on land, in which Indian survey took an early and important part. It was shown that the Gangetic alluvium, formerly looked upon as a marine deposit, was, as regards its upper layers at least, a land deposit; it was shown that the great series of sandstones and conglomerates of which the foot-hills of the Himalayas are composed were formed, not in the sea, but on land, by rivers which were the ancestors of those now draining the Himalayas; the great Gondwana system was shown to be exclusively a dry land deposit, and later the same origin was attributed to the great Vindhyan system.

In the next place we have the recognition of the Permian glacial epoch. The first description of these beds was published in the *Memoirs* of the Geological Survey in 1856, and their glacial origin proclaimed in 1875 by the late Mr. H. F. Blanford. Though the idea of glaciation in Permian times and in what are now low latitudes has met with great opposition, it has gradually made progress, and it is now generally recognised that the Permian boulder-beds of India, though extending into regions that are now within the tropics, are relics of a bygone glacial epoch. In Africa, the glacial origin of similar beds has been accepted by more than one observer; and in Australia—where the traces of glacial action in the marine Permian or Permo-Carboniferous beds, below the principal coal-measures, was first recognised by a member of the Indian Geological Survey who had been deputed by the Indian Government to study the Australian coal-measures—the existence of glacial action on a large scale has been fully confirmed by workers in that country. In South America, too, it seems that there are similar beds, of apparently the same age, and the evidence of this widespread glacial epoch, more remarkable in many ways even than the post-Tertiary extension of glaciation, must be reckoned with in any speculations attempting to account for the great climatic changes of which the past sediments bear witness.

The labours of the Indian Geological Survey have had important results in geological science in other minor points, too numerous to detail in the limited space of an article, but a mention of the great earthquake of 1897 cannot be omitted. This earthquake was the greatest of which there is historic record, exceeding the great Lisbon earthquake of 1755; but even before this was known the Indian Government had ordered the Survey to make a complete scientific investigation of it. Being the greatest earthquake of which there is historic record, the visible effects were on an unprecedented scale, and its investigation has consequently yielded results which must be taken into account in all future seismological research. Nor must mention be omitted of one of the most recent suggestions, which appears likely to be fruitful of results, made in 1898 by Mr. T. H. Holland, that much of the decomposition, and more especially hydration, of the minerals composing igneous rocks was submarine, and that the undecomposed state of similar rocks, even of perishable minerals like olivine and nepheline, in certain regions, is due to these being ancient land-areas which have not been submerged beneath the sea since a remote geological period.

Such, briefly stated, is the record of the Geological Survey of India, a record which reflects credit on all who have been concerned in the making of it. Yet it must not be forgotten that credit is due also to the Civil Administration of India, which has not only maintained the staff by whom the record has been made, but has given the further pecuniary assistance, modest in amount but steadily continued, which has enabled the Survey to form a museum fully illustrating the geology of India in all its branches, to establish a well-equipped laboratory, and to collect a library which, as a geological working library, is probably unsurpassed by any and equalled by few.

## *NOTES.*

M. DARBOUX, Dean of the Faculty of Sciences of Paris, has been elected permanent secretary of the Paris Academy of Sciences, in succession to the late M. Joseph Bertrand. Prof. J. Willard Gibbs, professor of mathematical physics in Yale University, has been elected a correspondant of the Academy in the section of mechanics. Prof. J. Chatin, assistant professor of histology at the Sorbonne, has been elected a member of the section of anatomy of the Academy, in succession to the late M. Blanchard.

THE recommendations of the international conference which recently met in London to determine the steps which might usefully be taken for the preservation of wild animals, birds and fish in South Africa, have now been published as a Parliamentary Paper. The zone within which it is proposed to apply the provisions of the Convention is bounded on the north by the 20th parallel of north latitude, on the west by the Atlantic Ocean, on the east by the Red Sea and by the Indian Ocean, on the south by a line following the northern boundary of the German possessions in South-Western Africa, from its western extremity to its junction with the River Zambesi, and thence running along the right bank of that river as far as the Indian Ocean. To preserve the various forms of animal life existing in a wild state within this zone, it is proposed to prohibit the hunting and destruction of certain animals, especially females when accompanied by their young or capable of being otherwise recognised, of which the protection, whether owing to their usefulness or to their rarity and threatened extermination, may be considered necessary by each local government. The establishment, as far as it is possible, of reserves within which it shall be unlawful to hunt, capture or kill any bird or other wild animal except those specially exempted from protection by the local authorities, is recommended, and also of close seasons with a view to facilitate the rearing of young. It is proposed to put export duties on the hides and skins of giraffes, antelopes, zebras, rhinoceroses and hippopotami, on rhinoceroses and antelope horns, and on hippopotamus tusks, and to prohibit the hunting or killing of young elephants. Measures are to be taken for ensuring the protection of the eggs of ostriches, and for the destruction of the eggs of crocodiles, of those of poisonous snakes, and of those of pythons. It is, however, understood that some of the principles laid down may be relaxed, either in order to permit the collection of specimens for museums or zoological gardens, or for any other scientific purpose.

PROF. J. PERRY, F.R.S., has been elected president of the Institution of Electrical Engineers for the session 1900–1901.

MR. BORCHGREVINK, who recently returned from his explorations in the Antarctic, will, it is expected, give a lecture before the Royal Geographical Society on June 18.

THE American Academy of Arts and Sciences has decided to award the Rumford medal to Prof. Carl Barus, of Brown University, for his researches in heat.

WE learn from *Science* that the Committee of Coinage, Weights and Measures of the U.S. House of Representatives has unanimously agreed to report as an amendment to the Sundry Civil Bill the measure establishing a United States Standardising Bureau, referred to in NATURE of May 17 (p. 61).

WE regret that a part of the edition of last week's NATURE appeared without the announcement that the names of Dr. D. Gill, F.R.S., and Dr. T. E. Thorpe, F.R.S., were included in the list of Birthday Honours. The former has been promoted to the rank of K.C.B., and the latter has been created a C.B.

THE third Liverpool expedition for the study of tropical diseases, referred to last week, will start in the first week in July. The members of the expedition are Drs. Durham and Walter Myers. The object of the expedition is to study yellow fever, malaria and dysentery.

AN excursion to Malvern and district has been arranged by the Geologists' Association for Whitsuntide. The director will be Prof. T. T. Groom, and during the stay at Malvern, from Saturday, June 2, to Tuesday, June 5, a number of interesting geological sections and structures will be examined.

A MEETING of the Yorkshire Naturalists' Union will be held at York on Whit-Monday for the investigation of the natural history of Askham Bog, and for the geological investigation of the morainic ridges of Askham and Bilbrough. Askham Bog is one of the very few undrained spots left in the Vale of York; hence the naturalist values it much as the palæontologist values one bone of an extinct animal, for from it he can draw such a true and interesting picture of a stage in the development of the district.

A FISHERIES Exhibition will be held at Salzburg, Austria, on September 2, and the eight following days. The exhibits are divided into nine classes, and include sections for artificial breeding apparatus, preserving methods, tackle, and the literature and statistics of fishing.

THE *Times* announces that the appointment of the commanding officer of the National Antarctic Expedition has been made by the joint committee of the Royal and Royal Geographical Societies. The officer selected is Lieut. Robert F. Scott, now torpedo-lieutenant of the *Majestic*. He has been fifteen years in the Navy, has a record of service of the highest class, and will shortly be promoted to commander. The head of the scientific staff will be Dr. J. W. Gregory, recently appointed professor of geology in the University of Melbourne. Though he has only just entered upon his duties at Melbourne, the authorities have granted him leave of absence to serve with the Antarctic Expedition. He will come to England in October to prepare for his new work.

AN exhibition of photographs, by Dr. P. H. Emerson, will be open at the Royal Photographic Society, 66 Russell Square, W.C., from May 30 until June 30.

BY the will of the late Prof. Piazzi Smyth, the executors are instructed to repay to the Government Grant Committee of the Royal Society all of the advances, estimated at 300*l*., made by the Society to Prof. Smyth for the purchase of scientific instruments after he went to Ripon. The will bequeaths to the Royal Society of Edinburgh the portrait of Prof. Smyth, by Faed, R.S.A., and all his books of original drawings and journals, and his boxes of glass photographs. The residuary estate is to be in trust for certain legatees for life, and subject to their life interest for the Royal Society of Edinburgh if agreeable to receive the same as a trust, whereof the income is to be employed by that Society, first, in printing for a limited free distribution and a small sale to the public, at a cost of about 600*l*., the spectroscopic MSS. offered by Prof. Smyth to the Government in October 1857, and then to assist or promote every ten or twenty years an exceptional expedition for the study of some particular branch of astronomical spectroscopy in the purer air of some mountain elevation of not less than 6000 feet above the sea-level, as tried and found feasible by him in the first experiment on the Peak of Teneriffe in 1856. If the residuary estate is not accepted by the Royal Society of Edinburgh, it is to be distributed amongst the pecuniary legatees.

LAST week the Royal Horticultural Society held its thirteenth "Temple Show." In every respect, apart from the uncertainty of the weather, the great annual exhibition more than fulfilled the expectation of lovers of flowers and of horticulturists generally. On the other hand, the botanist was greeted by no species that was not already known. The student of evolution might, nevertheless, have made the acquaintance of many new artificial races, and hours might have been spent in examining fresh garden "varieties," produced by hybridisation and cross-breeding. Even when some striking variation has been chanced upon, and "fixed" by careful selection, judicious crossing may be resorted to, in order that further "improvements" may be brought about. To take a case, Messrs. Laing and Sons showed some begonias, in which the development of a "crest" or tuft of small outgrowths from the petals was very much marked. This appeared sporadically and slightly at first in a plant with flowers of the same colour as those of its parents, but since the establishment of the crested race it has been crossed with others, and now crested petals may be had of many tints. The cactus-flowered zonal pelargonium may be mentioned on account of its vivid colouring and numerous narrow petals. Its rearer, Mr. E. S. Towell, obtained it from the seed of a "semi-double" *Pelargonium*, which he crossed with pollen from many different flowers. Among these was that of *Lychnis chalcedonica*; and Mr. Towell, though not absolutely certain of the fact, considers that the last-named species is the father of his "Fire Dragon." The particular tint of scarlet shown by the petals, the time these persist, and their divided appearance favour this view.

THE Sugar-Beet Committee of the Central Chamber of Agriculture have completed arrangements for a limited number of experiments in the growth of sugar-beet during the forthcoming season, each experimental plot being at least one acre in extent. In all, there will be about thirty-three different experiments, of which twenty-five are situated in England, four in Scotland, and four in Ireland. The English counties in which one or more experiments will be made are Wilts, Hants, Berks, Oxon, Beds, Kent, Suffolk, Hereford, Worcester, Warwick and Lancaster. As previous experiments have, in certain cases, demonstrated the value of sugar-beet for the feeding of live stock (independently of its value for the manufacture of sugar), it has been decided to keep this point specially in view in connection with the experiments of the present year.

AN interesting feature of the Paris Exposition is the elevated moving pavement. The line, which is described in the *Scientific American*, forms a complete circuit, running along the side of the Champ de Mars, the Quai d'Orsay, the Esplanade des Invalides and the Avenue de la Motte-Picquet, the total length of its course being 3500 metres. The platform is supported on an elevated structure, to which access is given from a number of stations situated within the Exposition grounds. The substructure supports three platforms, one fixed and two movable, these having a speed of eight and four kilometres per hour. To enable the platform to pass around the curves, the different sections are dovetailed into each other by large circular portions, forming a kind of horizontal hinge. Each of the platforms carries an I-beam running along under the centre; these rest upon a series of rollers placed at intervals, operated by electric motors. Upon the shaft of the motor is mounted a large roller for the high-speed platform and a roller of one-half the diameter for the slow speed. The friction of the platform is sufficient to cause its adhesion to the rollers. The platform was put into operation on April 14, and has proved a great success, as by its means an easy passage through the grounds is afforded, as well as a series of interesting views. The tour is made in twenty-six or fifty-two minutes.

PARTICULARS of the short electric line—about 5000 feet in length—between Earl's Court and High Street, Kensington, which has just been opened on the Metropolitan District Railway, are given in the current number of the *Electrician*. The engineers, Sir John Wolfe Barry and Sir W. H. Preece, were required to equip this line electrically without any interference with the permanent way, without any interference with the running of the ordinary train service, and without allowing any electric current to pass through the permanent way or the subsoil, lest such should interfere with the signalling arrangements of the line. In accordance with these stringent regulations, it became necessary to adopt an insulated system throughout, and to do the whole of the construction work in the few midnight hours when the trains were not running. The system may be termed a four-rail system. It includes the two ordinary track rails, which are not used for any electrical purpose whatever, and two electrical rail conductors placed on either side outside the track. A special type of train has been designed for the line, the design being such as to adapt it specially to the experimental conditions. There is no separate locomotive, the train being worked in block, and a motor carriage being placed at either end. Only one motor carriage, however, is used at a time—viz. that one in the front in the direction in which the train is moving. This arrangement, while duplicating the amount of electric motor plant, is convenient, as it obviates shunting the motor carriage. It is intended to carry out a series of careful experiments on electric traction upon this line, and for this purpose a dynamometer car will sometimes be attached to the train. Already certain experiments have been made. In his evidence before the Select Committee of the House of Commons considering the Manchester-Liverpool Express Railway, Sir William Preece recently stated that the train, fully loaded, had started on the very difficult gradient of 1 in 43—a feat which an ordinary steam locomotive was unable to perform when hauling a similar load. Moreover, in a tug-of-war between the electric train and a steam locomotive, the electric train readily overcame the steam engine.

IT has been said that every person is mentally a little unbalanced, and that education from this point of view is simply the attempt to secure and maintain mental equilibrium, which, however, is never actually attained. Lapses of thought, inadvertencies in expression, and other slips in speaking or writing (*lapsus linguae* and *lapsus calami*) are thus of interest to the psychologist as useful guides to the understanding of mental processes. Every one has experienced unaccountable lapses of this kind, and the lapse often comes as a surprise to the speaker or writer himself. During a lecture, a professor inadvertently referred to the "tropic of Cancercorn," intending to say "the tropics of Capricorn and of Cancer." Many similar instances might be cited, for example, the man who was going for a walk to "get a breash of freth air," the person who inquired for the "portar and mestle," and another who said "the pastor cut the shermon sort." A physicist is recorded to have said that he feared he should "get the instrument out of needle," when he intended to say he feared he would "get the instrument out of level and deflect the needle." This is curious, but it is not so amusing as the order of "beggs and acon" for breakfast, or the remark of a nervous churchman to a stranger in his seat, "Excuse me, but you are occupuing my pie." Mr. H. Heath Bawden has made a detailed study of similar mental lapses, both oral and graphic, and his results are described in a monograph of the *Psychological Review*. It is suggested that the aberrations dealt with are due to incipient aphasia or agraphia, and the similarity between them is held to show that our ordinary experience borders at every point on what is called the abnormal or pathological condition.

FOR some time past peat has been largely used in this country as litter for stables in the place of straw. This material is now likely to have a much more extended use, and the peat bogs of this and other countries made to assume a value never before realised. For the past twelve years Herr Zschörner, of Vienna, has been investigating the properties of peat, and has shown its possibilities. In the Vienna Exhibition of last year was a building in which everything, from the carpets on the floor to the curtains on the windows, and the paper on the walls, had all been made from peat. Herr Zschörner's investigations have shown that, although the fibres of the remains of the reeds and grasses of which peat is composed have become altered in their physical and chemical character, yet they have not suffered any anatomical change; and while nothing capable of fermentation or decay is left, the fibrous structure remains intact; that they are very durable, elastic, good non-conductors of heat and non-combustible. Fabrics woven from them are found to have the toughness of linen with the warmth of wool. There is no textile fabric that cannot be woven from these fibres. Blankets and other coverings used for horses and cattle have been found in use to excel in warmth and cleanliness. The unspun fibre is found to be a good substitute for absorbent cottons possessing strong antiseptic properties. Paper of several qualities has been made, and the uses to which peat fibre has already been applied indicate possibilities that may render the peat bogs of Ireland a valuable addition to the resources of that country, and give full occupation to the inhabitants of the "congested" districts.

THE *Rendiconto* of the Naples Academy for March and April contains a complete list of the mathematical works of the late Prof. Beltrami.

IN the *Bulletin de la Classe des Sciences* of the Belgian Academy, M. Vandenberghe continues his researches on the dissociation of substances in solution. The author, by new experiments conducted with the use of solvents belonging to the same homologous series, establishes the conclusion that the influence exerted on the decomposition of molecular associations by the solvent does not materially influence the effects due to elevation of temperature.

A PRELIMINARY note on the magnetic observations made during the *Belgica* Antarctic expedition is given by M. G. Lecointe in the *Bulletin de la Classe des Sciences* (Brussels). For the measurements of declination Neumayer's apparatus was used, the declination being the difference between the magnetic azimuth of a star and the true azimuth calculated from the local time. The Neumayer apparatus was also found far more suitable than the theodolite for measuring the horizontal component, the instability of the theodolite as its feet began to sink into the ice rendering observations made with it of little value. In determining the inclination the great sensitiveness of Gambey's compass could not be utilised regularly on account of the ice-movements, and here again Neumayer's apparatus proved the most serviceable. The paper consists chiefly of a table of the recorded observations.

IN his Wilde Lecture, published in the *Manchester Memoirs*, 1899, No. 5, Lord Rayleigh discusses the mechanical principles and possibilities of flight, both natural and artificial. The problem of the sailing bird is treated from the three alternative points of view, which attribute its source of energy to upward currents, variation of wind-velocity with the altitude and pulsating gusts of wind. Lord Rayleigh then considers the law of dependance of the aerial resistance of a plane surface on its obliquity, and describes experimental methods whereby the resistances at different obliquities may be compared by an "astatic" arrangement, in which pairs of vanes are so adjusted that the moments of the oppositely turned vanes balance each other. In connection with the expenditure of power required to support a given weight, Lord Rayleigh has calculated that, in order for a man to support himself by a *vertical* screw by working at the power an average man can maintain for eight hours a day, he would require a screw ninety metres in diameter, and in this estimate no account has been taken of the weight of the mechanism or of frictional losses. In conclusion, the effects of flapping wings are briefly discussed.

A FURTHER addition to Mr. H. C. Russell's interesting current papers (No. 4), containing the tracks of 124 bottles received during a year ending with September last, has been published. The comparatively large number of bottles received appears to be owing to the prevalence of southerly winds; the north-west winds being found to alter the direction of the drifting bottles, so that they pass to the south of Australia. The suggestion made in the previous paper that bottles thrown over on the east coast drifted first to the east in Tasman Sea, and then northwards until they reached the great current from the east, which passes south of New Caledonia, is supported in a remarkable way by the drift of the *Perthshire* after she was disabled in the Tasman Sea; her general direction for 640 miles was N.E. by N., at an average daily rate of 13·6 miles. Towards the end of the drift she travelled rapidly to the west. Two bottles floated near Cape Horn came over to Australia at the daily rates of 12·2 and 9·5 miles respectively. There are also some very interesting bottle tracks in the North Atlantic Ocean. One of these, floated in the Gulf of Mexico, made a run of 6300 miles in a south-easterly direction—the longest hitherto recorded in that ocean by Mr. Russell. The proportion of bottles received to those thrown overboard appears to be very disappointing; out of 48 bottles thrown from ss. *Gulf of Bothnia*, to take an extreme case, only one was received.

THE resolutions passed at the International Congress for Marine Research held at Stockholm last summer are published *in extenso* in the April number of the *Scottish Geographical Magazine*. An important feature in these resolutions is the recognition that the primary object of the investigations recommended to be undertaken is the improvement and promotion of fisheries by means of international agreements.

IN *Appleton's Popular Science Monthly* for May, Prof. E. S. Morse gives a full account of the observations made by himself many years ago as to the manner in which the larval insect known as the "cuckoo-spit" forms the mass of froth in which it is concealed. If the insect be cleared from the mass of froth and allowed to settle upon some succulent plant-stem, it will soon thrust its piercing organs through the outer layers and commence sucking the juices. After a short time a clear fluid exudes from the abdomen, and after flowing over the body eventually fills up the spaces between the latter, the legs and the stem, so that the entire creature is soon totally enveloped. For about half an hour the insect will remain quiescent in this condition, when it suddenly begins to "blow bubbles" by turning its tail out of the fluid, opening the terminal segment, which appears like claspers, and then bending down the tail into the fluid with an attached air-bubble, which is instantly allowed to escape. These movements are repeated at the rate of 70 or 80 a minute till the entire envelope of fluid is converted into the mass of froth with which we are all familiar.

*Bulletin* No. 23 of the Division of Entomology of the U.S. Department of Agriculture is devoted to a series of articles, by Mr. F. H. Chittenden, dealing with some of the insects injurious to garden crops. Sixteen different species of such pests are described, with the devastation they cause. Out of these, the most generally interesting is the invasion of the "fall army-worm" in 1899. This caterpillar (*Laphygma frugiperda*) derives its name from the circumstance that, unlike the true "army-worm," it is seldom observed, except perhaps in the most Southern States, to travel in large hosts until the autumn, or, at least, before August. During 1899 these caterpillars appeared in vast swarms over a large area of the States, where they inflicted much damage on crops of various kinds. Properly speaking, the "fall army-worm" is a grass-feeder, but when it makes its appearance in such numbers as to consume all accessible pasture in the neighbourhood, as was the case last season, it turns its attention to gardens, orchards and greenhouses. The crops affected last year, in addition to grass and clover, included rice, maize, wheat, oats, cabbage, beet, peas, turnips and even tobacco. Unfortunately, the "fal army-worm" differs from the true "army-worm" in that its hosts may reappear the year after a visitation; and destructive measures, such as poisoning by kerosene or arsenic, are accordingly essential.

WE have received the *Proceedings* of the South London Entomological and Natural History Society for 1899, which includes the President's address and several original communications on entomological subjects.

THE latest issue of the *Natural History Transactions* of Northumberland, Durham, &c., contains a catalogue of the unique and unrivalled collection of British birds presented in 1883 to the trustees of the Natural History Society of those counties by the late John Hancock. The catalogue has been drawn up by Mr. J. Howse.

THERE are already several excellent editions of Gilbert White's "Selborne," but a welcome will be extended to the splendid volumes, the first of which has just been published by Mr. S. T. Freemantle. In this edition we shall have in two volumes a superb "Natural History and Antiquities of Selborne, and a Garden Kalendar," edited by Dr. R. Bowdler Sharpe, with an introduction to the Garden Calendar by Dean Hole, and numerous plates and other illustrations.

"LA SPÉLÉOLOGIE" is the title of a little handbook by M. E. A. Martel on the science of caverns. It belongs to the "Scientia" series, published by MM. Carré et Naud (Paris, 1900; pp. 126). The author gives an account of the origin of fissures and caverns, of the action of subterranean waters and all matters connected with them. He deals also with the phenomena of ice-caves (*glacières*), and again with the relations between rock cavities and metalliferous deposits. The various prehistoric and historic remains found in caverns are somewhat briefly dealt with; and finally the author discourses on the plants and animals found living in subterranean regions.

MR. W. ENGELMANN, of Leipzig, has just commenced the publication of an elaborate work, by Prof. W. Wundt, entitled "Völkerpsychologie: Eine Untersuchung der Entwicklungsgesetze von Sprache, Mythus, und Sitte." The work will be completed in three volumes—the first dealing with language as the expression of the emotions by signs and speech, the second with myths and religions, and the third with ceremonies and customs. Each volume will be complete in itself, and will be separately indexed. The second (and concluding) part of the first volume will be published in the autumn of this year, and will then be reviewed with the part which has just appeared.

DR. ROBERT MUNRO'S "Rambles and Studies in Bosnia-Herzegovina and Dalmatia" (Blackwood) is not only an excellent book of travel, but a very valuable contribution to archæological literature. An appreciative notice of the work appeared in these columns four years ago (vol. liv. p. 78), and we have now to announce the publication of a second, revised and enlarged edition. An account is given of the proceedings of the Congress of Archæologists and Anthropologists held at Sarajevo in August 1894, and as the Government of Bosnia-Herzegovina have departed from their original intention to publish a report of the congress, Dr. Munro's volume has the distinction of being the only record, in book form, of the important problems which were considered. A number of additions have been made to the original volume, and a much-wanted index has been supplied.

THE second and third parts of the second volume of the unique "Encyklopädie der mathematischen Wissenschaften" in course of publication by the firm of B. G. Teubner, Leipzig, have just been issued. The scope of this great undertaking is so extensive that several years must elapse before the work is completed. There will be seven volumes in all, having the following subjects and editors:—Arithmetic and algebra, Prof. W. F. Meyer; analysis, Prof. H. Burkhardt; geometry, Prof. Meyer; mechanics, Prof. F. Klein; physics, Prof. A. Sommerfeld; geodesy and geophysics, Prof. E. Wiechert; astronomy (under arrangement); history, philosophy, and didactic questions, Prof. Meyer. The work is published under the auspices of the Munich and Vienna Academies of Science, and the Göttingen Society of Sciences, and no mathematical library will be complete without it.

SIR JOHN LUBBOCK'S book on "The Scenery of Switzerland, and the causes to which it is due" has been translated into Italian by Dr. L. Scotti, and is published by Signor U. Hoepli, of Milan, as "Le Bellezze della Svizzera, Descrizione del Paesaggio e sue Cause geologiche." The first English edition was noticed in NATURE of September 10, 1896 (vol. liv. p. 439); the translation is from the third edition, published in 1898.

THE use of acetylene for lighting rooms upon a commercial scale renders its purification from sulphuretted and phosphuretted hydrogen imperative, on account of the injurious effects of the products of combustion of these impurities in a confined space. Numerous substances have been put forward by different inventors as effecting the desired purification, among which may be mentioned ferric chloride, chromium sulphate, petroleum, benzene, chromic acid, bleaching powder, and cuprous chloride. The ideal purifier should remove the impurities as completely as possible, should not absorb acetylene itself, and should not communicate any objectionable properties to the purified gas. The current number of the *Moniteur Scientifique* contains abstracts of numerous papers upon this subject. From these it would appear that solutions of metallic salts do not wholly remove the impurities, chromic acid and chloride of lime solutions being the only substances that effect a complete purification, and of these the former is preferable, as with the latter explosions have occurred, probably owing to the formation of chloro-acetylene.

THE additions to the Zoological Society's Gardens during the past week include a Diana Monkey (*Cercopithecus diana*) from West Africa, a Common Squirrel (*Sciurus vulgaris*), British, presented by Mrs. Morris; a Common Paradoxure (*Paradoxurus niger*) from Java, presented by Mr. E. E. Hewens; a Boddaert's Snake (*Drymobius boddaerti*), a Chequered Elaps (*Elaps lemniscatus*), a Rat-tailed Opossum (*Didelphys nudicaudata*) from Trinidad, presented by Mr. Leon Bernstein; a Summer Snake (*Contia oestiva*), a Mexican Snake (*Coluber melanoleucus*), six Menobranches (*Necturus maculatus*), five American Green Frogs (*Rana halecina*) from North America, deposited.

## OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN JUNE.

June 2. 8h. 33m. to 9h. 35m. Moon occults κ Cancri (mag. 5·0).
4. 9h. 49m. to 10h. 45m. Transit of Jupiter's Satellite III. (Ganymede).
7. 9h. 58m. to 10h. 55m. Moon occults the star D.M. – 10°, 3570 (mag. 6·0).
11. 8h. Jupiter in conjunction with moon. Jupiter 1° 29′ North.
11. 11h. 23m. to 12h. 43m. Transit of Jupiter's Satellite III. (Ganymede).
12. Partial eclipse of the moon.
 13h. 16·2m. First contact with penumbra.
 15h. 24·2m. First contact with shadow.
 15h. 27·6m. Middle of the eclipse.
 15h. 31·0m. Last contact with the shadow.
June 12. 17h. 39·0m. Last contact with the penumbra.
 It will be a very small eclipse, the proportion of the moon's surface covered by the earth's shadow being equal to only one-thousandth part. The fainter outlying shadow will, however, cover a large region, but will be only faintly discernible.
13. 7h. Mercury in conjunction wtih ε Geminorum. Mercury, 0° 3′ South.
13. 9h. 40m. to 10h. 52m. Moon occults the planet Saturn.
15. Venus. Illuminated portion of disc, 0·144. Mars, 0·962.
16. 8h. 48m. Jupiter's Satellite IV. (Callisto) in conjunction south of planet.
19. Saturn. Polar semi-diameter, 17″·0. Outer minor axis of outer ring, 18″·87.
23. 5h. Saturn in opposition to sun.

SEARCH EPHEMERIS FOR EROS.—The following is continued from the ephemeris by J. B. Westhaver (*Astronomical Journal*, No. 479, vol. xx. p. 185).

*Ephemeris for 12h. Greenwich Mean Time.*

Prof. Howe is reported to have discovered the planet in the constellation Aries.

OXFORD UNIVERSITY OBSERVATORY.—In the twenty-fifth annual report of the Savilian professor at Oxford, Prof. H. H. Turner briefly reviews the history of the institution. The late Prof. Pritchard, in 1873, successfully appealed to the University for facilities to institute the means of carrying on astronomical research, but the plans originally projected being modified by the presentation of Dr. De la Rue's instruments, the building was not finished until 1875. However, notwithstanding his advanced age, Prof. Pritchard carried out before his death two important researches, the *Uranometria Nova Oxoniensis*, and the determination of stellar parallaxes; and initiated a third, the share of the Observatory in the International Astrographic Chart.

During the six years of Prof. Turner's directorship the energies of the Observatory have been chiefly directed to carrying out, as expeditiously and economically as is consistent with the necessary accuracy, this great work of fundamental astronomy. One or two more years will be required to complete it, but the work is at present as well advanced as at any of the other eighteen observatories which are collaborating. In addition, the Observatory has been utilised as an educational institution for the benefit of the students of the University.

For the Astrographic Catalogue, 736 plates are now measured, and 705 completely reduced, out of the 1180 falling to the share of the Observatory. Measurements have been made on a plate supplied by Prof. E. C. Pickering to determine the optical distortion of a photographic doublet. A preliminary discussion of these measures indicates a distortion varying as the cube of the distance from the centre of the plate; this somewhat surprising result, if confirmed, will enable the reduction of photographs of star fields of wide angle to be made with great accuracy.

ROUSDON OBSERVATORY, DEVON.—Sir C. E. Peek sends us another of his pamphlets (No. 6), containing the detailed particulars of the observations of variable stars during the past decade. The observations of T Cassiopeiæ extend over the ten years 1889–1898, and those of R Cassiopeiæ from 1887–1898. At the end of the observation the light curves of the two stars are shown.

## SOME MODERN EXPLOSIVES.[1]

### II.

I NOW pass to points which have to be considered when weighing the comparative merits of explosives for their intended ends.

You will easily understand that between explosives which are intended to be used for propelling purposes, and those which are intended to be used, say for bursting shell, a wide difference may exist.

In the former case, facility of detonation would be an insuperable objection; in the latter, the more perfect the detonation the better, certain special cases, to which I have not time to refer, excepted.

There exists, I think, considerable diversity of opinion as to what does, and what does not, constitute true detonation. I find many persons speak of a detonation, when I should merely consider that a very high pressure had been reached. This gun-cotton slab on the table affords me, I think, a fair opportunity of explaining my meaning. Were I to set fire to it, except for the large volume of flame and the great amount of heat generated, we in this room would not suffer; we should probably experience more inconvenience did I fire a similar slab of gunpowder, as detached burning portions would probably be projected to some distance.

But if I fired this same slab with two or three grammes of fulminate of mercury, a detonation of extreme violence would follow. The detonation would be capable of blowing a hole in a tolerably thick iron plate, and would probably put an end to a considerable portion of the managers in the front row.

I mentioned to you some time ago the time in which a charge would be consumed in the chamber of a gun—if a charge of 500 lbs. of these slabs were effectively detonated, this charge would be converted into gas in less than the 20,000th part of a second.

No such result would follow were I to try a similar experiment with a slab of compressed gunpowder of the same dimensions. I do not say the experience would be pleasant, but there would be nothing of the instantaneous violent action which marks the decomposition of the gun-cotton.

To give you an idea of the extraordinary violence which accompanies detonation, I have fired, for the purpose of this lecture, with fulminate of mercury, a charge of lyddite in a cast-iron shell, and those who are sufficiently near can see for themselves the result. By far the greater part of the cast-iron shell, weighing about 10 lbs., is reduced to dust, some of which is so fine that I assumed it to be deposited carbon until I had tested it with a magnet. I may add that the indentation of the steel vessel by pieces of the iron which were not reduced to powder would appear to indicate velocities of not less than 1200 feet-seconds, and this velocity must have been communicated to the fragments in a space of less than two inches.

For the sake of comparison, I place beside it a cast-iron shell burst by gunpowder. You will observe the extraordinary difference. I also have on the table two small steel shells exploded, one by a perfectly detonated, the other by a partially detonated charge. I may remark that in the accounts of correspondents from the seat of war, frequent mention is made of the green smoke of lyddite. This appearance is due probably to imperfect detonation—to a mixture, in fact, of the yellow picric with the black smoke. I do not say, however, that imperfect detonation is necessarily an evil.

To another experiment I draw your attention.

For certain purposes I caused to be detonated, in the chamber of a 12-pounder, a steel shell charged with lyddite. The detonation was not perfect, but the base of the shell was projected with great violence against the breech screw. You may judge of how great that violence was when I tell you that the base of the shell took a complete impression of the recess for the primer, developing great heat in so doing; but, what was still more remarkable, the central portion of the base also sheared, passing into the central hole through which the striker passes. This piece of shell is upon the table, and open to your inspection.

One other instance to illustrate the difference between combustion and detonation I trouble you with. Desiring to ascertain the difference, if any, in the products of explosion between combustion and detonation, I fired a charge of lyddite in such a manner that detonation did not follow. The lyddite merely deflagrated. But a similar charge differently fired shortly afterwards detonated with such extreme violence as to destroy the vessel in which it was exploded. The manner in which the vessel failed I now show you (Fig. 4), and I have on the table the internal crusher gauge which was used, and which was also totally destroyed.

The condition of this gauge is very remarkable, and the action on the copper cylinder employed to measure the pressure was one to which I have no parallel in the many thousand experiments I have made with these gauges. The gauge itself is fractured in the most extraordinary way, even in some places to which the gas had no access, and the copper cylinder, which when compressed usually assumes a barrel-like form (that is, with the central diameter larger than that at the ends as shown in Fig. 5); but in this experiment, and in this only, the cylinder was bulged closed to the piston, as you see. It would appear as if the blow was so suddenly given that the laminæ of the metal next the piston endeavoured to escape in the direction of least resistance, that being easier than to overcome the inertia of the laminæ below.

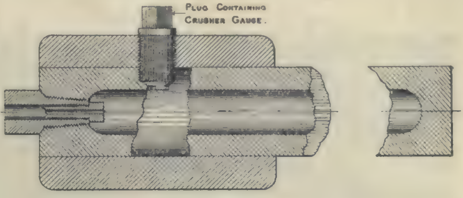

FIG. 4.—Explosion vessel.

The erosive effect of the new explosives is another point of first-rate importance in an artillery point of view. The cordite of the service is not, if the effect be estimated in relation to the energy impressed on the projectiles, more erosive than, for example, brown prismatic, which was itself a very erosive powder; but as we are able to obtain, as you have seen, very much higher energies with cordite than with brown prismatic, the erosion of the former is, for a given number of rounds, materially higher.

There is, however, one striking difference. By the kindness of Colonel Bainbridge, the Chief Superintendent of Ordnance Factories, I am enabled to show you a section of the barrel of a large gun eroded by 137 rounds of gunpowder. Beside it is a barrel of a 4·7-inch quick-firing gun eroded by 1087 rounds of gunpowder, and another eroded by 1292 rounds of cordite. You will observe the difference. In the former case the erosion much resembles a ploughed field. In the latter the appearance is more, as if the surface were washed away by the flow of the highly heated gases.

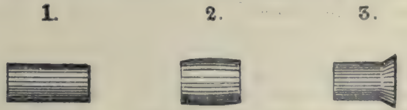

FIG. 5.—Copper cylinders.

But take it in what way you please, the heavy erosion of the guns of the service, if fired with the maximum charges, is a very serious matter, as with the large guns, accuracy, and in a smaller degree energy, are rapidly lost after a comparatively small number of rounds have been fired.

Cordite was first produced for use in small arms only, where, owing to the small charges employed, the question of erosion is not of the same importance as with large guns; but its employment, from the great results obtained with it, was rapidly extended to artillery, and the attention of my friends, Sir F. Abel and Prof. Dewar, has for some time been devoted in conjunction with myself to investigating whether it is not possible materially to reduce this most objectionable erosion.

With this object I made the following series of experiments.

---

[1] A Discourse delivered at the Royal Institution on Friday, March 23, by Sir Andrew Noble, K.C.B., F.R.S. Continued from p. 90.

I had cordite of the same dimensions prepared with varying proportions of nitro-glycerine and gun-cotton. The nitro-glycerine being successively in the proportions of 60, 50, 40, 30, 20 and 10 per cent., and with each of these cordites I determined the following points:—

(1) The quantity of permanent gases generated.

(2) The amount of aqueous vapour formed.

(3) The heat generated by the explosion.

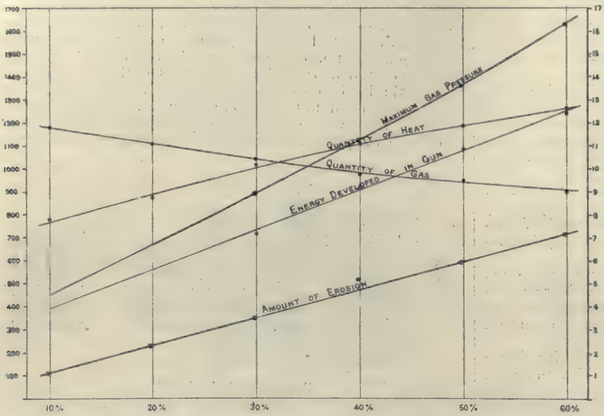

Fig. 6.—Energy in foot tons; heat in units; gas in c.c.; erosion in inches; pressure in tons.

(4) The erosive effect of the gases.

(5) The ballistic energy developed in a gun, and the corresponding maximum pressure.

(6) The capacity of the cordite to resist detonation when fired with a strong charge of fulminate of mercury.

The results of these experiments were both interesting and instructive.

To avoid wearying you with a crowd of figures, I have placed on Fig. 6 the results of the first five series of experiments.

On the axis of abscissæ are placed the percentages of nitro-glycerine, while the ordinates show the quantities of the gases generated, the amount of heat developed, the erosive effect of the explosive, the ballistic energy exhibited in a gun, and the maximum gaseous pressure.

You will note that with the smallest proportion of nitro-glycerine the volume of permanent gases is a maximum, and that the volume steadily decreases with the increase of nitro-glycerine. On the other hand, the heat generated as steadily increases with the nitro-glycerine, and if we take the product of the quantity of heat and the quantity of gas as an approximate measure of the potential energy of the explosive, the higher proportion of nitro-glycerine has an undoubted advantage; but in this case, as in the case of every other explosive with which I have experimented, the potential energies differ less than might be expected from the changes in transformation, as the effect of a large quantity of gas is to a great extent compensated by a great reduction in the quantity of heat generated.

This effect is, of course, easily explained, and was very strikingly exhibited in the much more complicated transformation experienced by gunpowders of different compositions, a long series of which were very fully investigated by Sir F. Abel and myself.

Looking at this diagram you will have observed that the energy developed in the gun is very much smaller with the smaller proportions of nitro-glycerine, but if you will look at the corresponding maximum pressure-curve you will note that the pressures have decreased nearly in like proportion. Hence it is probable that the lower effect is mainly due to a slower combustion of the cordite, and it follows that this effect may be, to a great extent, remedied by increasing the rate of combustion by reducing the diameter of the cordite to correspond with the reduction in the quantity of nitro-glycerine.

To test this point I caused to be manufactured a second series of cordites of the same composition, but with the diameters successively reduced by ·03, as you see with the samples I hold, and this diagram (Fig. 7) shows at a glance the result. The energies you see are, roughly, practically the same, but if you look at the pressure-curve you will observe that I have obtained a curve in which, on the whole, the pressures vary in the contrary direction, that is to say, in this case the pressures increase as the nitro-glycerine diminishes.

Taking the two series into account, they show that by a proper arrangement of amount of charge and diameter of cord it would be possible to obtain the same ballistics and approximately the same pressure from any of the samples I have exhibited to you.

But I have to draw your attention to another point. From the curve showing the quantities of heat you will note that in passing from 10 per cent. nitro-glycerine to 60 per cent., the heat generated has increased by about 60 per cent. But here is the curve indicating the corresponding amount of erosion, and you will see that while the quantity of heat is only greater by about 60 per cent., the erosion is greater by nearly 500 per cent.

These experiments entirely confirm the conclusion at which I have previously arrived, viz. that heat is the principal factor in determining the amount of erosion.

In experimenting with a number of alloys of steel, the greatest resistance was shown by an alloy of steel with a small proportion of tungsten, but the difference between the whole of these amounted only to about 16 per cent.

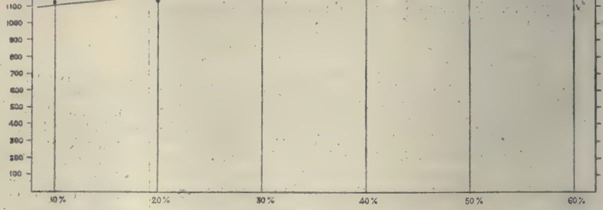

Fig. 7.—Energy in foot tons; pressure in tons.

The whole of these cordites were, as I have mentioned, subjected to detonation tests. None of them, so far as my experiments went, exhibited any special tendency in this direction.

I will now endeavour to describe to you a most interesting and important series of experiments which, I regret to say, is a long way from completion.

The objects of these experiments were (1) to ascertain the time required for the combustion of charges of cordite in which the cordite was of different thicknesses, varying from 0·05 inch to 0·60 of an inch; (2) the rapidity with which the explosives part with their heat to the vessel in which the charge is confined; and (3) to ascertain, if possible, by direct measurement, the temperature of explosion, and to determine the relation between the pressure and temperature at pressures approximating to those which exist in the bore of a gun, and which are, of course, greatly above any which have yet been determined.

As regards the first two objects I have named, I have had no serious difficulties to contend with, but as regards the third, I have so far had no satisfactory results, having been unable to use Sir W. Roberts Austen's beautiful instrument owing to the temperature at the moment of explosion being greatly too high, high enough indeed to melt and volatilise the wires.

I am, however, endeavouring to make an arrangement by which I hope to be able to determine these points when the temperature is so far reduced that the wires will no longer be fused.

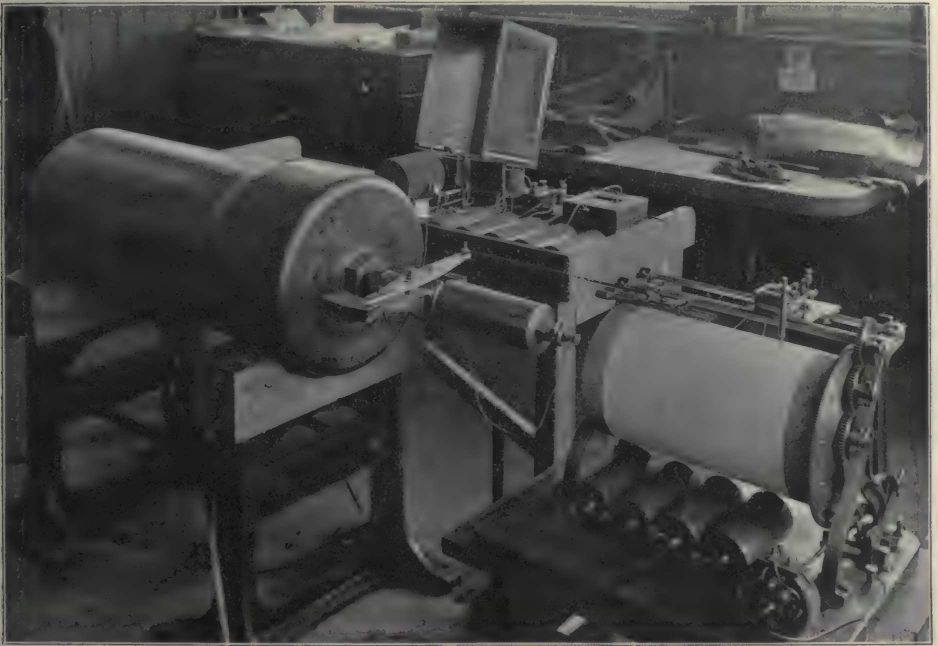

FIG. 8.

The apparatus I have used for these experiments is placed on the table. The cylinder in which the explosives were made is too heavy to transport here, but this photograph (Fig. 8) will sufficiently explain the arrangement. The charge I used is a little more than a kilogramme, and it is fired in this cylinder in the usual manner.

The tension of the gas acting on the piston compresses the spring, and indicates the pressure on the scale here shown. But to obtain a permanent record, the apparatus I have mentioned is employed.

There is, you see, a drum made to rotate by means of a small motor. Its rate of rotation is given by a chronometer acting on a relay, and marking seconds on the drum, while the magnitude of the pressure is registered by this pencil actuated by the pressure-gauge I have just described.

To obtain with sufficient accuracy the maximum pressure, and also the time taken to gasify the explosive, two observations—that is, two explosions—are necessary.

If the piston be left free to move the instant of the commencement of pressure, the outside limit of the time of complete explosion will be indicated; but, on account of the inertia of the moving parts, the pressure indicated will be in excess of the true pressure, and the excess will be, more or less, inversely as the time occupied by the explosion.

If we desire to know the true pressure, it is necessary to compress the gauge beforehand to a point closely approximating to the expected pressure, so that the inertia of the moving parts may be as small as possible—the arrangement by which this is effected is not shown in the photograph, but the gauge is retained at the desired pressure by a wedge-shaped stop, held in its place by the pressure of the spring, and to the stop a heavy weight is attached—when the pressure is relieved by the explosion, the weight falls and leaves the spring free to act.

I have made a large number of experiments with this instrument, both with a variety of explosives and with explosives fired under different conditions. Time will not permit me to do more than to show you on the screen three pairs of experiments to illustrate the effect of exploding cordite of different dimensions, but of precisely the same composition.

I shall commence with rifle cordite. In this diagram (Fig. 9) the axis of abscissæ has the time in seconds marked upon it, while the ordinates denote the pressures, and I draw your attention to the great difference, in the initial stage, between the red and the blue curves. You will notice that the red curves show a maximum pressure some 4½ tons higher than that shown by the blue curve; but this pressure is not real. It is due to the inertia of the moving parts. The red and blue curves in a very small fraction of a second come together, and remain practically together for the rest of their course. The whole of the charge is consumed in something less than fifteen thousandths (·015) of a second.

In the case of the blue curve the maximum pressure indicated is obtained in the way I have described, and is approximately correct—about nine tons per square inch. The rapidity with which this considerable charge parts with its heat by communication to the explosion vessel is very striking. In four seconds after the explosion the pressure is reduced to about one-half, and in twelve seconds to about one-quarter.

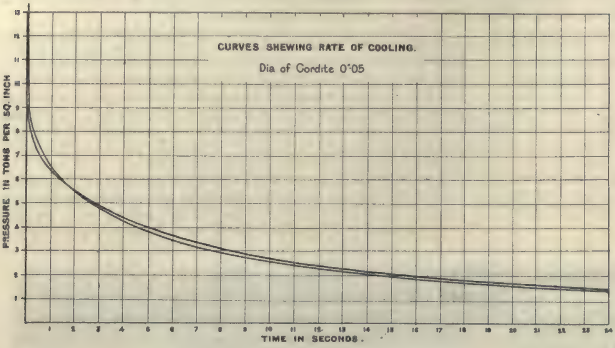

FIG. 9.

I now show you (Fig. 10) similar curves for cordite 0·35 inch in diameter, or about fifty times the section. Here you see that the time taken to consume the charge is longer. The effect of inertia is still very marked, although much reduced. The true maximum pressure is little over 8 5 tons, but after the first third of a second the two curves run so close together that they are indistinguishable.

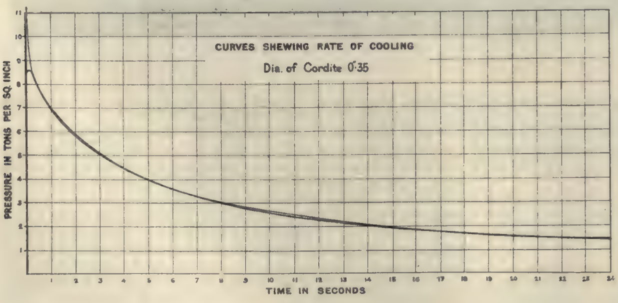

FIG. 10.

Again, you see the pressure is reduced by one-half in four seconds, and in a little more than twelve seconds again halved.

The last pair of curves I shall show (Fig. 11) you was obtained with cordite 0·6 inch in diameter, or nearly 150 times the section of the rifle cordite. With this cordite the combustion has been so slow that the effect of inertia almost disappears; it is reduced to about half a ton per square inch. The maximum being nearly the same as in the last set of experiments. The time of combustion indicated I have called slow, but it is about ·06 of a second, and the whole of the experiments show a most remarkable regularity in their rate of cooling, the pressures at the same distance of time from the explosion being in all cases approximately the same—as, indeed, they ought to be. The density being the same and the explosive the same, the only difference being the time in which the decomposition is completed.

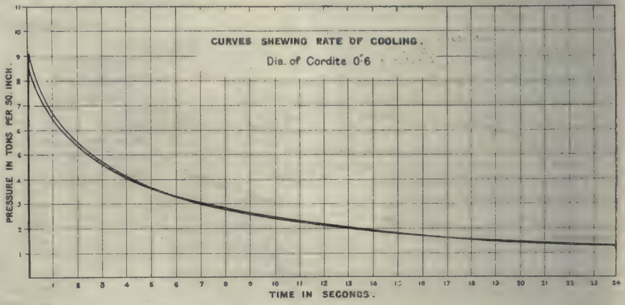

FIG. 11.

It appears to me that, knowing from the experiments I have described, the volume of gas liberated, its composition, its density, its pressure, the quantity of heat disengaged by the explosion; and knowing all these points with very considerable accuracy, we should be able, from the study of the curves to which I have drawn your attention, and which can be obtained from different densities of gas, to throw considerable light upon the kinetic theory of real, not ideal gases, at temperatures and pressures far removed from those which have been the subject of such careful and accurate research by many distinguished physicists.

The question, as I have said, involves some very considerable difficulties; nevertheless, I am not without hope that the experiments I have been describing may, in some small degree, add to our knowledge of the kinetic theory of gas.

That wonderful theory faintly shadowed forth almost from the commencement of philosophic thought, was first distinctly put forward by Daniel Bernoulli early in the last century. In the latter half of the century now drawing to a close the labours of Joule, Clausius, Clerk Maxwell, Lord Kelvin and others have placed the theory in a position analogous and equal to that held by the undulatory theory of light.

The kinetic theory has, however, for us artillerists a special charm, because it indicates that the velocity communicated to a projectile in the bore of a gun is due to the bombardment of that projectile by myriads of small projectiles moving at enormous speeds, and parting with the energy they possess by impact to the projectile.

There are few minds which are not more or less affected by the infinitely great and the infinitely little.

It was said that the telescope which revealed to us infinite space was balanced by the microscope which showed us the infinitely small; but the labours of the men to whom I have referred have introduced us to magnitudes and weights infinitesimally smaller than anything that the microscope can show us, and to numbers which are infinite to our finite comprehension.

Let me draw your attention again to this figure (Fig. 2) showing the velocity impressed upon the projectile, and let me endeavour to describe the nature of the forces which acted upon it to give it its motion. I hold in my hand a cubic centimetre, a cube so small that I daresay it is hardly visible to those at a distance. Well, if this cube were filled with the gases produced by the explosion at 0° C. and atmospheric pressure, there would be something over seven trillions, that is, seven followed by eighteen cyphers, of molecules. Large as these numbers are, they occupy but a very small fraction of the contents of the cubic centimetre, but yet their number is so great that they would, if placed in line touching one another, go round many times the circumference of the earth, a pretty fair illustration of Euclid's definition of a line.

These molecules, however, are not at rest, but are moving, even at the low temperature I have named, with great velocity, the molecules of the different gases moving with different velocities dependent upon their molecular weight. Thus, the hydrogen molecules which have the highest velocity move with about 5500 feet-seconds mean velocity, while the slowest, the carbonic anhydride molecules, have only 1150 feet-seconds mean velocity, or about the speed of sound.

But in the particular gun under discussion, when the charge was exploded there were no less than 20,500 cubic centimetres of gas, and each centimetre at the density of explosion contained 580 times the quantity of gas—that is, 580 times the number of molecules that I mentioned. Hence the total number of molecules in the exploded charge is 8⅓ quadrillions, or let us say approximately for the total number eight followed by twenty-four cyphers.

It is difficult for the mind to appreciate what this immense number means, but it may convey a good idea if I tell you that if a man were to count continuously at the rate of three a second, it would take him 265 billions of years to perform the task of counting them.

So much for the numbers; now let me tell you of the velocities with which, at the moment of explosion, the molecules were moving. Taking first the high-velocity gas, the hydrogen, the molecules of the gas would strike the projectile with a mean velocity of about 12,500 feet-seconds. You will observe I say mean velocity, and you must note that the molecules move with very variable velocities. Clerk Maxwell was the first to calculate the probable distribution of the velocities. A little more than one-half will have the mean velocity or less, and about 98 per cent. will have 25,000 feet-seconds or less. A very few, about one in 100 millions, might reach the velocity of 50,000 feet-seconds.

The mean energy of the molecules of different gases at the same temperature being equal, it is easy from the data I have given to calculate the mean velocity of the molecules of the slowest moving gas, carbonic anhydride, which would be about 2600 foot-seconds.

I have detained you, I fear, rather long over these figures, but I have done so because I think they throw some light upon the extraordinary violence that some explosives exhibit when detonated. Take, for instance, the lyddite shell exploded by detonation I showed you earlier in the evening. I calculate that that charge was converted into gas in less than the 1/60,000th part of a second, and it is not difficult to conceive the effect that these gases of very high density suddenly generated, the molecules of which are moving with the velocities I have indicated, would have upon the shell.

The difference between the explosion of gunpowder fired in a close vessel, and that of gun-cotton or lyddite when detonated, is very striking. The former explosion is noiseless, or nearly so. The latter, even when placed in a bag, gives rise to an exceedingly sharp metallic ring, as if the vessel were struck a sharp blow with a steel hammer.

But I must conclude. I began my lecture by recalling some of the investigations I described in this place a great many years ago. I fear I must conclude in much the same way as I then did, by thanking you for the attention with which you have listened to a somewhat dry subject, and by regretting that the heavy calls made on my time during the last few months have prevented my making the lecture more worthy of my subject and of my audience.

## EXTENSIONS OF THE DYEING DEPARTMENT OF YORKSHIRE COLLEGE.

The opening of the extensions in the Clothworkers' Departments of Yorkshire College, Leeds, has already been referred to (p. 69). The new buildings, which are shown in the accompanying illustration, comprise practical and pattern dyehouses and a research laboratory; and, as with several other parts of Yorkshire College, they owe their erection to the generous interest taken in technical education by the Clothworkers' Company of London.

The Clothworkers' Departments of the Yorkshire College consist of textile industries, dyeing and art. The buildings occupied by these departments have been erected by the Clothworkers' Company at a cost of about 60,000*l.*; they are spread over an area of about one-and-a-half acres, and have been specially arranged and equipped for the teaching of all the subjects connected with the designing and manufacturing of woven fabrics.

The Dyeing Department of the Yorkshire College was established in 1880, and the head of the department is Prof. J. J. Hummel. Although the accommodation at first provided was extremely limited, it nevertheless sufficed to show that a demand for instruction in dyeing really existed, and that a continuous supply of students for this subject was available. In due time it was found desirable to increase the facilities for experimental work, and in 1885 the Clothworkers' Company of London erected and equipped, at an expense of about 12,000*l.*, the front portion of the handsome and commodious building at present occupied.

New Buildings of the Dyeing Department of Yorkshire College.

It was felt some years ago that the work of the different departments might be connected. It was considered desirable, for example, that the coloured yarns employed in the weaving department should be dyed by the students in the dyeing department, so that, if at the same time these yarns could also be manufactured on the premises by the establishment of a spinning department, it would become possible to teach the whole routine of clothworking, from the wool in the raw state to the finished cloth. Acting upon this idea, the Clothworkers' Company decided to make the necessary provision for carrying out the scheme suggested, and to extend both the weaving and dyeing departments, at a cost of about 25,000*l.* In connection with the dyeing department, it was arranged to build a three-storied building, to provide two additional dyehouses in which practical dyeing could be carried on, and also a research laboratory for the prosecution of scientific investigations connected with dyestuffs and dyeing.

In July 1896, the foundation stone of the new Clothworkers' Research Laboratory and the other extensions was laid by the

Master of the Clothworkers' Company, and the completed buildings were opened on May 11.

At the present time, therefore, the dyeing department of the Yorkshire College is represented by a building of considerable dimensions, and so comprehensive in character and equipment as practically to meet every requirement for the purpose of giving a complete theoretical and practical instruction in the art of dyeing in all its branches.

Some idea of the magnitude of the work done in the dyeing department of Yorkshire College may be gained from the fact that each session over 200,000 dyed patterns are distributed. Each student, according to the time spent in the dyehouse, receives during his course of instruction from 2000 to 20,000 patterns, each of which conveys a definite piece of information on some point connected with the application of this or that colouring matter. Not only is the behaviour in the dyebath of each colouring matter investigated, but notes of the results obtained are made by the students during the progress of the work. Further, each student enters in his own book all the patterns received, together with notes of the materials employed, and the results of each experiment. Hence the students not only learn how to experiment and discover the capabilities of each colouring matter for themselves, but they also acquire the useful habit of observing and of making notes, while their pattern books contain a fund of information which is invaluable to them in their after career. The systematic training which they receive also prepares them to deal with the variable conditions of work in actual practice, such as the character of the water, the nature of the textile material employed and its ultimate uses, and many other points which must always be taken into account in dyeing.

In the practical and pattern dyehouses the students are shown how they are expected to apply in practice the principles they have learned in the course of their experimental work. Moreover, the solution of difficulties which naturally arise under the slightly altered conditions from those obtaining in the experimental dyehouse, the greater confidence inspired by dealing with the larger quantities of material, and the knowledge that the products of their labour are really to be employed in the manufacture of cloth, are all factors of inestimable value in the training of the students before they enter into actual practice, to which they are as it were brought indeed one step nearer by the character of the work pursued. Altogether, the students are able, in the College dyehouses, to gain at least some insight as to the meaning and value of practical experience, and an influence is exerted which reacts by giving life and vigour to the work of the whole department.

The art of dyeing owes much to science, and in a University College like the Yorkshire College, it is not unreasonable to expect that students of the art should, in return, contribute something to science, more particularly to that branch of it which pertains to dyeing. If in the experimental and practical dyehouses the students are taught the *art* of dyeing, in the Clothworkers' Research Laboratory they are also urged to study the *science* of dyeing. The aim here is to assist in the work of gaining a fuller and truer knowledge of the fundamental laws and principles connected with dyestuffs and dyeing, and so help to raise, as far as possible, the whole tone and level of the dyeing trade, by infusing into it the traits of an exact science. The carrying on of original research by advanced students has already become, indeed, a marked feature of the department, and the Clothworkers' Company have, in a special way, recognised the value of such work by establishing a lectureship, the holder of which devotes his whole time to co-operating with the professor in introducing students to this higher form of study.

This research work, too, has an intimate connection with Prof. Hummel's lectures, in the course of which are described the methods employed in preparing the coal-tar colours, in isolating the pure colouring principles of dyewoods, and in studying the chemistry of mordanting, dyeing, &c. By allowing the students to carry out similar experiments themselves, the College enables them to understand, in a clearer manner than is otherwise possible, how our knowledge concerning dyestuffs and dyeing has been acquired, and it is hoped that by reason of the practical experience thus gained in the art of research, some students may, in due time, become independent investigators.

The Clothworkers' Research Laboratory is an addition which gives completeness to the means of instruction in dyeing already furnished. The advanced students are thereby provided with the facilities for extending the boundaries of science connected with dyeing, and it is hoped that many young men will take advantage of the opportunity thus given. If in the pursuit of this object the authorities at Yorkshire College can succeed in attracting and training a band of earnest workers; if a well-recognised and successful School of Research in Dyeing is established, side by side with the School of Practical Dyeing, it cannot but be of inestimable value from an educational as well as from a practical point of view, for, if the students, before they leave the College, are taught to contribute to the general sum of knowledge it it surely education in the truest and best sense of the term.

## *MR. NIKOLA TESLA'S RECENT ELECTRICAL EXPERIMENTS.*

A REMARKABLE paper, by Mr. Nikola Tesla, appears in the June number of the *Century Magazine*. The subject is "The Problem of Increasing Human Energy, with Special Reference to the Harnessing of the Sun's Energy"; and though metaphysical and sociological questions receive a large share of attention, the article contains an account of some very interesting electrical experiments, now described for the first time, illustrated by several very striking photographs, two of which are here reproduced. Mr. Tesla has been engaged for several years in further investigating the properties of alternate currents of high potential and frequency, with which he astonished audiences at the Royal Institution in 1892 (see NATURE, vol. xlv. p. 345). The following abstract of a part of his paper shows that his work has led to results of scientific interest and significance.

Electrical discharges capable of making atmospheric nitrogen combine with oxygen have recently been produced. Experiments made since 1891 showed that the chemical activity of the electrical discharge was very considerably increased by using currents of extremely high frequency or rate of vibration. This was an important improvement, but practical considerations soon set a definite limit to the progress in this direction. Next, the effects of the electrical pressure of the current impulses, of their wave-form and other characteristic features, were investigated. Then the influence of the atmospheric pressure and temperature and of the presence of water and other bodies was studied, and thus the best conditions for causing the most intense chemical action of the discharge and securing the highest efficiency of the process were gradually ascertained. The flame grew larger and larger, and its oxidising action more and more intense. From an insignificant brush-discharge a few inches long it developed into a marvellous electrical phenomenon, a roaring blaze, devouring the nitrogen of the atmosphere and measuring sixty or seventy feet across (Fig. 1). The flame-like discharge visible is produced by the

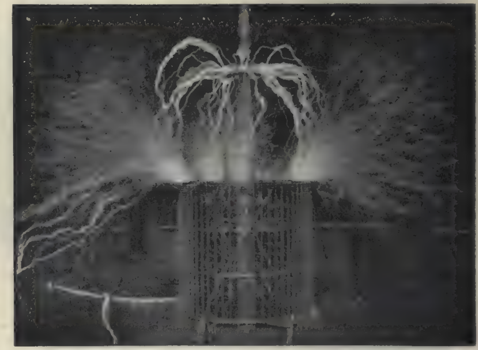

FIG. 1.—Combustion of atmospheric nitrogen by the discharge of an electrical oscillator giving twelve million volts and alternating 100,000 times per second. The flame-like discharge shown in the photograph measured 65 feet across.

intense electrical oscillations which pass through the coil shown, and violently agitate the electrified molecules of the air. By this means a strong affinity is created between the two normally indifferent constituents of the atmosphere, and they combine readily, even if no further provision is made for intensifying the chemical action of the discharge.

Under certain conditions the atmosphere, which is normally a high insulator, assumes conducting properties, and so becomes capable of conveying any amount of electrical energy. The discovery of the conducting properties of the air, though unexpected, was only a natural result of experiments in a special field carried on for some years previously. It was during 1889 that certain possibilities, offered by extremely rapid electrical oscillations, led to the design of a number of special machines adapted for their investigation. One of the earliest observations made with these new machines was that electrical oscillations of an extremely high rate act in an extraordinary manner upon the human organism. Thus, for instance, powerful electrical discharges of several hundred thousand volts, which at that time were considered absolutely deadly, could be passed through the body without inconvenience or hurtful consequences. Another observation was that by means of such oscillations light could be produced in a novel and more economical manner, which promised to lead to an ideal system of electric illumination by vacuum-tubes, dispensing with the necessity of renewal of lamps or incandescent filaments, and possibly also with the use of wires in the interior of buildings.

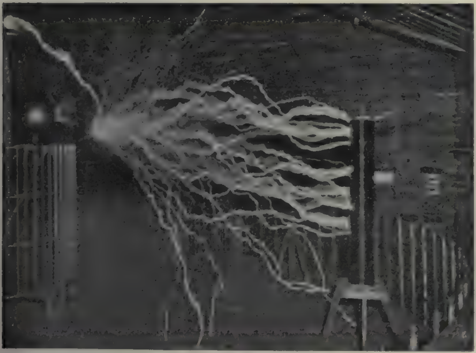

Fig. 2.—The coil, partly shown in the photograph, creates an alternating current of electricity at the rate of 100,000 alternations per second. The discharge escapes with a deafening noise, striking an unconnected coil 22 feet away, and creating such an electrical disturbance that sparks an inch long can be drawn from a water-main at a distance of 300 feet from the laboratory.

The investigations led to other valuable observations and results, one of the more important of which was the demonstration of the practicability of supplying electrical energy through one wire without return. To what a degree the appliances have been perfected since the demonstrations in 1892, when the apparatus was barely capable of lighting one lamp, will appear from the fact that as many as four or five hundred lamps have been lighted in this manner.

The success of this method of transmission suggested that the earth could be used as a conductor, thus dispensing with wires. The earth was regarded as an immense reservoir of electricity, which could be disturbed effectively by a properly designed electrical machine. Accordingly efforts were directed toward perfecting a special apparatus which would be highly effective in creating a disturbance of electricity in the earth, and a novel kind of transformer or induction-coil, particularly suited for this special purpose, was designed. By means of this apparatus, it is practicable, not only to transmit minute amounts of electrical energy for operating delicate electrical devices, but also electrical energy in appreciable quantities.

However extraordinary the results exemplified by Fig. 2 may appear, they are but trifling compared with those which are attainable by apparatus designed on these same principles. Electrical discharges have been produced, the actual path of which, from end to end, was probably more than one hundred feet long; but it would not be difficult to reach lengths one hundred times as great. Electrical movements occurring at the rate of approximately one hundred thousand horse-power have been obtained, but rates of one, five, or ten million horse-power are easily practicable.

The most valuable observation made in the course of these investigations was the extraordinary behaviour of the atmosphere toward electric impulses of excessive electromotive force. The experiments showed that the air at the ordinary pressure became distinctly conducting, and this opened up the wonderful prospect of transmitting large amounts of electrical energy for industrial purposes to great distances without wires, a possibility which, up to that time, was thought of only as a scientific dream. Further investigation revealed the important fact that the conductivity imparted to the air by these electrical impulses of many millions of volts increased very rapidly with the degree of rarefaction, so that air strata at very moderate altitudes, which are easily accessible, offer, to all experimental evidence, a perfect conducting path, better than a copper wire, for currents of this character.

The experiments have indicated that, with two terminals maintained at an elevation of not more than thirty thousand to thirty-five thousand feet above sea-level, and with an electrical pressure of fifteen to twenty million volts, the energy of thousands of horse-power can be transmitted over distances which may be hundreds and, if necessary, thousands of miles. Investigations are now being carried on with the object of reducing considerably the height of the terminals now required.

---

## *SOME SCIENTIFIC ASPECTS OF TRADE.*

A REPORT on the trade and commerce of Leghorn, for the year 1899, by Mr. Vice-Consul Carmichael, has just been received at the Foreign Office and published as No. 2714 of the Annual Series. The following extracts from the report are of interest as showing the various points at which scientific work and knowledge touch industry.

The proportion of sulphate of copper imported from Great Britain in 1898 was 96 per cent.; it had in 1899 fallen to 76 per cent. The explanation of this unwelcome fact appears to be due to keen United States competition. Italian manufacture is likely to become an even more formidable danger in the near future. Manufacturers appear as a rule to have gone to England for the greater part of the raw material, and that of itself was a handicap. Now, however, the flourishing and influential Società Metallurgica of Leghorn is busily erecting the necessary plant for the manufacture of sulphate of copper on a large scale. Italy produces some 26,000 tons of copper annually, and it is said that the company can depend upon securing its material at home. Should this be the case it will at once be seen how formidable a competitor is entering the field. In any case the more satisfactory days of the English trade in sulphate seem to be over.

As this series of reports is yearly obtaining a larger circulation it may perhaps be necessary to state that the wood from which briar pipes are made is not the root of the briar rose, but the root of the large heath known in botany as the *Erica arborea.* Our "briar" is but a corruption of the French "bruyère." The briar-root industry has had a somewhat curious history. First begun in the Pyrenees some 50 years ago, it travelled along the French Riviera and the Ligurian coast (taking Corsica by the way) to the Tuscan Maremma, and has now reached Calabria in the south, which is at present its most flourishing centre. By the very nature of the business, when a certain district has been exhausted of all its roots, the industry must come to an end there, and I have heard the opinion expressed that the Italian branch of it cannot last much more than another ten years. Leghorn has always been the centre of the export of Tuscan briar-root since the Maremma industry came into existence, but as the South Italian briar is of admittedly superior quality, a large quantity of the Calabrian root is also imported into Leghorn for selection and subsequent export.

The olive oil crop throughout Tuscany, small as it promised to be, has, I regret to say, been more than half destroyed by the ravages of the olive fly. Hence the quantity of olive oil obtained this season in Tuscany has been insignificant, while the quality of most of it is distinctly inferior. A full crop of olive oil may be reckoned at a money value of some 10,000,000*l.*

The olive maggot—which subsequently develops into the olive fly—destroys the pulp of the fruit, and so potent are the ravages of this pest that it is capable of diminishing the yield of oil by one-half, and seriously injuring the quality of the remainder. It will therefore be seen that the fly may actually cause damage in one year amounting to 5,000,000*l.* Notwithstanding the urgency of the matter, no means of destroying the insect appear so far to have been discovered, nor has the State suggested any practical remedy. The subject is recommended to the notice of English men of science, as any discovery which should exterminate the plague ought certainly to be profitable. What seems to be wanted is that entomologists of experience should carefully study the habits of the fly with a view to finding out the hitherto undiscovered winter habitat. Then alone could proper steps be taken for its destruction. It has been hazarded with some likelihood that the winter habitat of the fly must be in the bark of the olive trees. If that were the case, all that would be needed would be to paint the trees during the winter with a simple solution of lime, which, though it might spoil the beauty of the Italian landscape, would rid the country of a very formidable enemy to its agricultural prosperity.

---

## *UNIVERSITY AND EDUCATIONAL INTELLIGENCE.*

CAMBRIDGE.—Two University lectureships in experimental physics are now vacant. The appointment is for five years, and the stipend 50*l.* a year. Applications should reach the Vice-Chancellor by June 2.

The researches of Mr. L. N. G. Filon, advanced student, of King's College, in relation to certain problems in applied mechanics, have been approved as a qualification for the B.A. degree.

Sixty-three men and nineteen women have acquitted themselves so as to deserve honours in the Mathematical Tripos, Part I.

Honorary degrees will, on June 12, be conferred on the Earl of Rosse, F.R.S., Sir Benjamin Baker, F.R.S., Sir W. L. Buller, F.R.S., Prof. S. P. Langley, Prof. W. M. Flinders Petrie and Prof. H. Poincaré.

The graces for the establishment of a new special examination in agricultural science for the B.A. degree was opposed on May 24, but it was carried by a large majority. The first examination will take place at the end of the year.

ONE of the chief difficulties which has to be overcome by Technical Education Committees is the defective character of elementary education, respecting which lament is very general. Several instances of this difficulty are given in the current number of the *Record of Technical and Secondary Education.* The Durham committee have been compelled for some years to give financial assistance to preparatory classes now formed in all but twenty-one districts of the county. The committee have by such means paved the way for their new regulation of 1899 that there must be "the production of evidence of preparatory training on the part of all new applicants on whom attendance grants would be claimed." This action already appears to be having a satisfactory effect. The Cambridgeshire, Nottinghamshire and Staffordshire committees also deal at some length with the question of defective elementary education. The Cambridgeshire committee go so far as to say:—"The very backward state of elementary education has made it extremely difficult, if not impossible, to establish a system of technical education in the proper sense of the term." The Staffordshire committee speak of it in its relation to "the early age at which pupils leave the elementary schools," and this has thrown upon them "much elementary and preparatory work which otherwise would have been unnecessary." The importance of promoting the efficiency of the work of evening continuation schools cannot be too strongly urged, as they largely constitute the foundation of the work of Technical Education Committees and thus lead on to higher and specialised instruction.

## *SOCIETIES AND ACADEMIES.*

### LONDON.

**Physical Society,** May 25.—Prof. J. D. Everett, F.R.S., Vice-President, in the chair.—Prof. S. P. Thompson showed some experiments illustrating the aberration called Coma. If a converging lens is placed obliquely in a parallel beam of light, instead of giving a point image, it produces unilateral distortion, and the bright central spot is accompanied by a pear-shaped tail, which is known as a coma. The direction in which this tail points depends upon the side of the lens which is presented to the light. With a concavo-convex lens the convex surface gives an inward pointing coma, and the concave surface an outward pointing coma. The existence of this phenomenon is due to unequal magnification from different zones of the lens, a fact which was shown by covering the lens with a zone-plate of three or four rings and viewing on a screen the distorted images of the several zones. The form of a coma varies greatly with the distance of the screen from the lens. A parallel beam of light which has passed obliquely through a convex lens is capable of producing some curious shadows. The shadow of a rod can be obtained as a circular spot, and that of a grating, made by stretching threads between two rods, as concentric circular rings. Prof. Thompson also showed a stringed model illustrating the paths of light-rays in the formation of a coma.—Mr. R. T. Glazebrook then read some notes on the measurement of some standard resistances. Three methods have been employed by the author for building up multiples of a standard resistance, such as a one-ohm coil. The first method consists in making as accurately as possible three three-ohm coils. These in parallel can be compared directly with the standard by Carey Foster's method. Their resistance in series is very approximately nine times that in parallel, and hence an accurate determination of a resistance about nine ohms can be obtained. If, then, this resistance is put in series with the standard, an accurately-known ten-ohm resistance is obtained. By a similar process, a hundred- or a thousand-ohm coil can be built up. The second method consists in calibrating a resistance-box. The one-ohm coils of the box are compared directly with the standard, and the other resistances determined accurately by a building-up process, using a subsidiary resistance-box. In comparing the high resistances, the difference between the two boxes may be so great as to send the balance off the bridge wire. In these cases the third method is employed. The equal arms of the bridge are accurately known, and one of them is shunted with a resistance, which need not be accurately known, until the reading is brought back on to the wire. The coils chiefly used throughout the experiments are made of platinum-silver.—Mr. J. J. Guest read a paper on the strength of ductile materials under combined stresses. The author throughout his experiments has used the "yield point" of a material as the true criterion of its strength, and has rejected the elastic limit as being modified by local yielding. At present, two theories are used in the calculation of strengths of materials. The first is that the material yields when one of the principal stresses reaches a certain amount. This theory, which was adopted by Rankine and is used by engineers in England and America, is not in accord with recent experiments. The second theory is that the material yields when the greatest strain reaches a certain amount. This was advocated by St. Venant, and is used by engineers on the Continent. Besides these there is a third theory of elastic strength, in which the condition of yielding is the existence of a shearing stress of a specific amount. In the case of a solid bar subjected to torsion, there is a variation in the strain from the axis outwards, and consequently the materials have been used in the form of thin tubes. This allows the application of an internal fluid pressure. The specimens were of steel, copper and brass, the state of set caused by drawing having been removed by annealing. The tubes were subjected to (1) torque, (2) torque and tension, (3) tension only, (4) tension and internal pressure, (5) torsion and internal pressure, and (6) internal pressure only. The axial elongation, the twist, and occasionally the circumferential strain were measured. Towards the end of the experiments observations were made on bending. The results disprove the maximum stress theory, and are at variance with the maximum strain theory. The maximum shearing stress developed, and the corresponding shearing strain were comparatively constant throughout the experiments, and no other simple relation between the stresses or strains was even approximately constant. The results of the experiments have been plotted synoptically on a curve, and the several lines have been drawn upon which these points should lie, according to the various theories. It is readily seen that the points cluster round the line which represents the existence of a specific shearing stress. The author, therefore, favours the existence of this stress for any material. The chairman read a communication upon the subject from Dr. Chree. Mr. Guest, in his paper, has regarded the shearing stress theory as a little known one. As the shearing stress is half the difference between the greatest and least principal stresses, this theory is the same as Prof. G. H. Darwin's maximum stress-difference theory. All the theories suppose that the stress-strain law is linear, and that strains are so small that their squares and products can be neglected. Mr. Guest concludes that in ordinary materials the law is linear to the elastic limit, which answers to a stress lower than that which answers to the yield point, and that yield point phenomena arise between these. Nevertheless, he focusses attention on the yield point as the criterion of strength, and assumes that Hooke's law holds up to it.

**Entomological Society**, May 2.—Mr. W. L. Distant, Vice-President, in the chair.—Mr. W. L. Distant exhibited the cocoon, measuring nearly three and a half inches each way, of a Coprid beetle—probably belonging to the genus *Heliocopris*—found at Pretoria in the Transvaal.—The Rev. Theodore Wood exhibited a specimen of *Carabus auratus*, L., taken in either June or September 1898 by Mr. Ferrand, of Littlefield House, Exmouth, on the Haldon Hills in the neighbourhood of that town.—Mr. McLachlan exhibited an example of *Rhinocyphea fulgidipennis*, Guérin, a brilliant little dragon-fly of the subfamily *Calopteryginae*, a native of Cochin China, which, so far as he knew, had not been captured since prior to 1830. It had been in M. Guérin's hands, and Mr. McLachlan had received it from M. René Oberthür.—Mr. T. A. Chapman exhibited various specimens illustrating *Acanthopsyche opacella*.—Mr. Barrett exhibited specimens of Heterocera destructive to the fruit crops of South Africa. Among them *Sphingomorpha monteironis*, Butl., known as the Fruit Moth in Cape Colony—a bold and powerful insect, with a sucking tongue strong enough to pierce the sound skin of a peach or fig. The presence of a light does not appear to disturb it, so that examination of its methods can be readily made, when it can be seen that it does not take advantage of the natural opening into a fig, or of a crack or other injury to a peach, but deliberately pierces a hole which afterwards shows as a small round spot, from which decay invariably results. It seems a matter of indifference to the moth whether the fruit has fallen, or is on the tree, ripe or unripe. With regard to *Achaea lienardi* and *Serrodes inara*, the two species are restless and timid, and therefore more difficult to observe. In the present season, however, both have been extremely abundant, and have been seen at apparently uninjured fruit, so that it seems they are capable of equal destruction. Several others, feeding mainly on damaged fruit, were also taken with the aforesaid species, among them some new to science, and recently described by Sir George Hampson. Mr. Jacoby exhibited *Callomorpha wahlbergi* from Africa, and *Spilopyra sumptuosa* from Australia.—A paper was communicated on "New Palæarctic Pyralidæ," by Sir George F. Hampson, Bart.

**Anthropological Institute**, May 15.—Mr. C. H. Read, President, in the chair.—The president alluded to the severe loss which the Institute and anthropology in general had sustained in the loss of its former president, the late General Pitt-Rivers.—Mr. F. Haverfield contributed a note on certain stone objects discovered on a Roman site at Clanville, in Hants, and a discussion ensued from which it appeared improbable that they were of human workmanship.—Mr. J. Allen Brown described a collection of stone implements brought from Pitcairn Island by Lieut. Pike, R.N. The implements are of two types, both formed of the volcanic rocks of the island. The first series consists of stone axes of analogous forms to those of other islands of the Pacific. The other is peculiar, being large, and with incurved sides and broad cutting edge, more or less ground as well as chipped. A third form is that of a cylindrical chisel. The author mentioned also the discovery of rock carvings of sun, moon, birds, &c., tombs with pottery and human skulls, and of carved stone figures like those of Easter Island. The fact that the implements were found below the surface of the ground, and that from the time of its discovery by Carteret until its occupation by the mutineers of the *Bounty*, makes it probable that the remains in question are of considerable age.—Mr. H. Stopes exhibited a number of unclassified stone objects which he had collected from the river gravels of the Thames valley, and discussed the purposes for which he believed them to have been shaped. He also produced specimens of *Neritina fluviatilis* found in the same gravels, which he regarded as an indication of their age.

**Zoological Society**, May 22.—Dr. Albert Günther, F.R.S., Vice-President, in the chair.—A communication was read from Prof. G. B. Howes, F.R.S., and Mr. H. H. Swinnerton, on the development of the skeleton of the Tuatera, *Sphenodon* (*Hatteria*) *punctatus*, which was stated to be the outcome of eighteen months' work on materials supplied to the authors by Prof. Dendy, of Christchurch, N.Z An account was given of the egg, the hatching, and the habits of the hatched young, which the authors reared till four months old.—The Malacostracan Crustacea collected by Mr. Rupert Vallentin at the Falkland Islands, from December 1898 to February 1899, formed the subject of a paper by the Rev. T. R. R. Stebbing, F.R.S. Many of the species had long been known, as several scientific expeditions had been made to these islands during this century. This carefully made collection, however, had afforded a much needed opportunity for discussing and clearing up obscure points in some of the earlier descriptions of the Crustacean fauna.—Mr. L. A. Borradaile read the fourth instalment of his memoir on Crustaceans from the South Pacific. This part contained an account of the crabs, of which 77 species were enumerated. Seven new species were described, and a scheme of classification of the swimming crabs (*Portunidae*) was put forward.—A communication was read from Dr. R. Bowdler Sharpe, which contained an enumeration of the birds—56 species in all—collected during the Mackinder Expedition to Mount Kenya, accompanied by field-notes of the collectors.—Mr. F. E. Beddard, F.R.S., read a paper, entitled "A Revision of the Earthworm Genus *Amyntas*." According to the author, this genus comprised 102 species, which were enumerated and commented upon.—Mr. Beddard also read a paper on the structure of a new species of earthworm, which he proposed to name *Benhamia budgetti*, after its discoverer, Mr. J. S. Budgett, who had obtained two specimens of it at M'Carthy's Island during his recent visit to the Gambia.

PARIS.

**Academy of Sciences**, May 21.—M. Maurice Lévy in the chair.—Researches on the formation of nitric acid during combustions, by M. Berthelot. The compressed oxygen used in combustions in the calorimetric bomb always contains a small quantity of nitrogen, up to 8 per cent. A portion of this is oxidised during the combustion, and the amount of nitric acid so formed has been regularly measured in order to correct the calorimetric data. The author now attempts to trace the relation between the nature of the organic substance under combustion and the quantity of nitric acid formed, details being given in the present paper of experiments on amorphous carbon, graphite and diamond.—Limits of combustibility by red-hot copper oxide of hydrogen and methane diluted with large volumes of air, by M. Armand Gautier. When combustible gases, such as hydrogen or marsh gas, are mixed with large quantities of air and are passed over columns of red-hot copper oxide, the difficulty of completely burning the gas increases with the dilution. Thus with a dilution of 20 parts in 100,000, hydrogen is not completely burnt on passing over a column of 35 centimetres of red-hot copper oxide, but combustion is complete when this length is doubled. Methane is more difficult to burn; thus at a dilution of 7 in 100,000 nearly half the carbon escaped unburnt after passing over a column of oxide 70 cm. long.—Publications of the Observatory of Besançon from 1886 to 1896, by M. Lœwy.—Action of hydrogen bromide upon dextro-rotatory benzylidene camphor, by MM. A. Haller and J. Minguin. Benzylidene camphor combines with hydrobromic acid to form mono-bromo-benzyl-camphor. If the combination is carried out at 100°, two other products are obtained, benzylidene-campholic acid,

$$(\mathrm{COOH}).\mathrm{C_8H_{14}}.\mathrm{CH{:}CH}.\mathrm{C_6H_5},$$

and phenyloxy-homocampholic acid,

$$(\mathrm{COOH}).\mathrm{C_8H_{14}}.\mathrm{CH_2}.\mathrm{CH(OH)C_6H_5},$$

derivatives of which are described.—On fossil forests and the vegetative soils of the coal-measures, by M. Grand'Eury. Further arguments in favour of the author's view that the vegetable fossils have really grown in the places where they now occur, and have not been deposited there by water.—

Report on works presented by M. Marx.—Remarks on an eruption of the volcano Mayon in the Isle of Lucon, by the French Consul for the Philippines.—On the convergence of the coefficients in the development of the perturbation function, by M. A. Férand.—Remarks on a memoir of M. Massau on the graphical integration of some partial differential equations, by M. J. Coulon.—On a remarkable point in relation with the Joule-Thomson effect, by M. Daniel Berthelot. The point at which the inversion of the Joule-Thomson effect occurs is deduced by a graphical construction from the data of Amagat, and the result compared with some recent calculations of M. Van der Waals.—On the distribution of currents and potentials in the periodic state set up in the length of a symmetrical polyphase line presenting capacity, by M. Ch. Eug. Guye.—On resonance in wireless telegraphy, by M. A. Blondel.—Communication by wireless telegraphy with the aid of radioconductors with polarised electrodes, by M. C. Tissot.—On anhydrous calcium dioxide and the constitution of its hydrates, by M. de Forcand. A thermochemical paper.—On some properties of aluminium, and on the preparation of gaseous hydrogen phosphide, by M. Camille Matignon. Details are given showing how to burn aluminium in steam, carbon monoxide and dioxide, oxides of nitrogen, formic acid, sulphur dioxide and other gases and vapours. The preparation of crystallised aluminium phosphide is described, from which pure $PH_3$ can be readily obtained.—Combinations of lithium bromide with ammonia, by M. J. Bonnefoi.—The compounds $LiBr.NH_3$, $LiBr.2NH_3$, $LiBr.3NH_3$, $LiBr.4NH_3$ are indicated by a study of the dissociation pressures. The application of the Clapyron formula to these data gives values for the heats of dissociation of these compounds in good agreement with the direct thermochemical measurements.—On two polysulphides of lead and copper, by M. F. Bodroux. The compounds $PhS_5$ and $Cu_2S_5$ are described.—On a mercury chlorosulphide, by M. F. Bodroux. A chlorosulphide, $Hg_2S_5.HgCl_2$, can be prepared, which is stable at ordinary temperatures.—Action of water upon mercurous sulphate, by M. Gouy.—Partial synthesis of lævo-rotatory erythritol, by M. L. Maquenne. Wohl's method is applied to xylose, the steps being xylosoxime, acetylxylonic nitrile, erythose-acetamide, and erythrite.—Preparation of the dialkylamido-dichloranthraquinones, by M. E. C. Severin.—On a monoiodohydrin of glycol, by MM. E. Charon and Paix-Séailles.—On γ-chlorocrotonic acid, by M. R. Lespieau. A description of the properties of $CH_2Cl.CH:CH.CO_2H$, its nitrile and ethyl ester.—On the composition of the albumen of the St. Ignatius bean and of the *nux vomica* bean, by MM. Em. Bourquelot and J. Laurent. The albumen from these beans yields the same carbohydrates, a mixture of a mannane and a galactane, as the albumen of leguminous beans previously studied. In *nux vomica* the proportion of galatose found on hydrolysis is very high. These beans, in fact, serve as an advantageous source of crystallised galatose.—Experimental researches upon the evolution of the lamprey, by M. E. Bataillon.—Remarks upon certain points in the life-history of the lower organisms, by M. J. Kunstler.—On some new Synclavellæ in the compound Ascidians, by M. Maurice Caullery.—Analysis of marine deposits collected off Brest, by M. J. Thoulet.—The mineral matters in the human fœtus during the last five months of pregnancy, by M. L. Hugonenq.—Identity of a bacillus from milk with the pneumobacillus of Friedlænder, by MM. L. Grimbert and G. Legros. The complete identity of these bacilli was shown by a comparative study of their general biology and morphology, and of their action upon carbohydrates.

## DIARY OF SOCIETIES.

### *THURSDAY*, May 31.

Royal Society, at 4.30.—Palæolithic Man in Africa: Sir John Evans, F.R.S.—On the Estimation of the Luminosity of Coloured Surfaces used for Colour Discs: Sir W. de W. Abney, F.R.S.—The Sensitiveness of Silver and of some other Metals to Light: Major-General Waterhouse.—The Crystalline Structure of Metals (Second Paper): Prof. Ewing, F.R.S., and W. Rosenhain.—Vapour-density of Bromine at High Temperatures (Supplementary Note): Dr. E. P. Perman and G. A. S. Atkinson.

## MODERN PHYSICAL CHEMISTRY.

*The Theory of Electrolytic Dissociation.* By H. C. Jones. Pp. xii + 289. (New York: The Macmillan Company. London: Macmillan and Co., Ltd., 1900.)

THE theory of electrolytic dissociation is only some fifteen years old, but in that short time its growth has been very great, and its suggestiveness most marked. We gladly welcome a volume on the subject by one who has himself done much to promote its advance, and to render more secure some of the positions it has taken.

The author's preface explains his object; he has been asked from time to time where an account of the newer developments of physical chemistry is to be found. Original memoirs are not always accessible to a student, and in many cases explanation is wanted, and further development of an argument or line of thought may prove helpful; and so Mr. Jones has given us a book based in the main directly on the work of van 't Hoff, Ostwald, Arrhenius and the others who have made the theory, but in which the numerous developments of Arrhenius' original idea are skilfully brought together, and the bearing of the theory on phenomena, apparently widely diverse, is clearly shown. The plan of the book is in the main a good one. The first chapter is devoted to the earlier physical chemistry with the object of showing its relation to that which was to follow; accounts are given of Kopp's work on the boiling points of liquids and on molecular volumes, of the researches of Lorentz, Gladstone and Dale, Le Bel and van 't Hoff and Perkin on optical properties. The investigations of Favre and Silbermann, Berthelot and Julius Thomsen into thermal chemistry, the electrolytic work of Faraday and Clausius, Hittorf and Kohlrausch, are described; and an interesting and important discussion of the development of chemical dynamics and chemical statics concludes the chapter.

In the explanation of Guldberg and Waages' Law of Mass Action, there is a vague and somewhat unsatisfactory use of the word *force*; we are told that

> "if we represent the active masses of two substances by $m$ and $n$, and the coefficient depending on the nature of the substance, &c., by $c$, the force of the chemical reaction is expressed by $mnc$."

"Force" has no meaning used in this connection, the mass of compounds, or the number of molecules of compounds produced, can clearly be put equal to $mnc$, and the condition of equilibrium will be reached when this mass is equal to the mass of matter combining to form the original substance. There is an obvious misprint on page 62; $k'/k$ is clearly written for $c'/c$ of page 61.

In Chapter ii. we are introduced to the main subject of the book. An account is given of van 't Hoff's original paper "The Rôle of Osmotic Pressure in the Analogy between Solutions and Gases" (*Zeitschrift für physikalische Chemie*, i. p. 481), and the grounds for believing that in certain solutions the osmotic pressure conforms exactly to the three gaseous laws of Boyle, Gay Lussac and Avogadro are stated. Attention is here drawn to the large class of compounds, all the acids, all the bases, and all the salts, which form exceptions to the above statement. For these the law is no longer $PV = RT$, but $PV = iRT$, where $i$ is a coefficient always greater than unity, to which a meaning is given when we consider the work of Arrhenius.

According to this the molecules in an electrolyte, or some of them, are dissociated into ions. The electrolytic effects depend on the dissociated or active molecules; let these be $n$ in number, and suppose each is divided into $k$ parts; suppose also that there are $m$ molecules remaining inactive or undissociated, then the total number of molecules is $m + n$, the number of inactive molecules and ions is $m + kn$, and the value of van 't Hoff's coefficient $i$ is shown to be $(m + kn)/(m + n)$.

Arrhenius' theory of electrolysis is an extension of that of Clausius. Clausius had shown that in an electrolyte it was necessary to suppose some molecules of the dissolved salt were broken up into ions; Arrhenius explained how to determine from observations on osmotic pressure the number of such molecules in a given solution.

From this we are led on to two interesting chapters—"Evidence for the Theory" and "Applications of the Theory"; the evidence which the author has accumulated is most valuable, while the fertility and resourcefulness of the theory are strikingly shown. The book will be very useful; at the same time, in one respect, it is open to criticism of some importance. A student not unnaturally asks, What is osmotic pressure due to? Why, under certain circumstances, does liquid run into a closed vessel apparently against the pressure? What is the mechanism by which such a process is managed? It may be answered, We do not know! The author may fairly wish to use language independent of any molecular theory, and not bind himself down in any way; it is enough for many purposes, it may be said, to know that there is a definite pressure in such a solution without inquiring how that pressure is caused. At the same time it is impossible to avoid alluding to molecular impacts and the like; there is no evidence that Mr. Jones does wish to avoid it, and in places, *e.g.* p. 95 and elsewhere, he refers to the modern kinetic theory of gases, and we think—this is the criticism—that it would have made the book clearer if he had based his explanation throughout on the extension of that theory to liquids. When an ordinary experiment for measuring osmotic pressure is started with a solution inside a vessel closed with a semi-permeable membrane, the number of water molecules which strike a unit of area of the interior surface in any given time is less than the number striking the same area on the outside; thus more molecules of water enter the space than leave it; the molecules of the salt cannot pass the membrane, hence the pressure inside increases. The tendency is both for the water and the dissolved substance to distribute themselves uniformly; the pressure inside is due to the impacts (1) of the water, (2) of the dissolved substance that outside arises from the impacts of the water only; ultimately the pressures due to the water balance, and the excess of pressure inside measures the effect due to the impacts of the dissolved substance.

The whole is merely an example of the first proposition of Mr. Jones' third chapter. The physical properties of completely dissociated substances should be additive. This is all implied in the book; it might with advantage be stated more precisely.

G

Another matter with regard to which a greater definiteness seems desirable, even at the expense of some generality, is the theory of the action of the voltaic cell.

Nernst's theory of the electrolytic "solution-tension" of a solid—solution-pressure is a preferable term—is stated in his own words, but they are vague :

> "We must ascribe," it is said, after a reference to osmotic pressure, "to a dissolving substance in contact with a solvent, similarly, a power of expansion, for here also the molecules are driven into a space in which they exist under a certain pressure. It is evident that every substance will pass into solution until the osmotic partial pressure of the molecules in the solution is equal to the 'solution-tension' of the substance" (pp. 231-232).

We may put the whole theory slightly differently, thus :—

In the case when a substance is being dissolved in such a way that *molecules* pass from the solid into the liquid, the pressure rises in consequence of the impacts of these molecules on the walls of the containing vessel ; now when molecules also pass from the liquid into the solid, the "evident" fact is that the steady state is reached when the numbers entering and leaving the liquid are the same. In such a case the osmotic pressure measures the solution-pressure, and no electrical action is involved.

But now let us suppose that a metal is passing, not in the form of *molecules*, but in that of *ions* into water. Each of these ions carries with it a positive charge ; the water therefore tends to become positive, the metal negative, and an electrical double layer is formed over the surface of separation. The charged ions are not free to move throughout the water, but few escape from the surface ; hence the additional pressure due to the impacts of the metallic ions—the solution-pressure, as it is called—is small.

Again, let us take the case of a metal, such as copper, in a solution of one of its own salts, say copper sulphate ; here, also, if there were no electrical effects, we might suppose that copper *molecules* would be deposited out of the sulphate on to the metal, while other molecules would leave the metal ; the steady state would be reached when these two sets of molecules became equal in number, and the osmotic pressure would become—in reality, unless the solution were very weak, would *fall* to—the solution pressure. But according to the theory, the copper passes as *ions* which carry with them out of the solution their positive charge ; this they give up to the metal on becoming molecules. And since we suppose that, unless the solution be very weak, the number of copper ions leaving it is, to start with, greater than those entering, the metal becomes positive, the negative ions of the solution are attracted to it, the positive ions driven off, a double layer is again formed ; a difference of electrical potential is established between the metal and the solution—the metal being positive, the solution negative.

If, however, we consider a metal, such as zinc, which has a high solution pressure when immersed in, say, zinc sulphate, we must suppose that at the start more metallic ions leave the metal than enter it, the solution thus becomes positive, the metal negative, and the double layer formed is one which tends to prevent the positive metallic ions from leaving the zinc, and is thus opposite to that formed on the copper.

In both these cases we must suppose, when the steady state is reached, that the ions leaving the metal leave it under the solution pressure of the metal in the liquid. This may be seen as follows : If there were no electrical force called into action, the pressure would go on changing in the liquid up to the solution pressure, when the number of metallic ions leaving the surface would balance those entering.

Thus the solution pressure measures the whole amount of momentum which the ions of the metal tend to transfer per second across unit area of the surface. Now according to the theory this momentum depends on the metal only, and the tendency to transfer momentum remains the same, however the transfer be stopped ; in reality, the electrical forces acting across the double layer stop it, not the opposing momentum of the liquid ions, and the pressure exerted by these electrical forces must be therefore equal to the solution pressure of the solid, *i.e.* when a current is flowing the positive ions start from the metal at the solution pressure of the metal, and become, when in the solution, ions at the osmotic pressure of the liquid.

Now, however, let us suppose that a piece of copper is connected to the zinc, the two being dipped into zinc sulphate ; and suppose further, for simplicity, that there is no action at the interfaces zinc-copper or copper-liquid, then negative electricity from the zinc passes over to the copper through the zinc-copper junction, attracting to itself the positive ions in the solution and destroying the double layer at the zinc-liquid junction ; thus a current of positive electricity passes through the solution from zinc to copper. The source of the E.M.F. is at the zinc-liquid junction, arising from the fact that more zinc ions pass from the zinc into the solution than from the solution into the zinc ; or, as Nernst would put it, that the solution pressure of the zinc is greater than the osmotic pressure of the liquid. In reality, of course, there may be actions at both the other junctions similar in character to that which we have supposed to go on at the junction of the zinc and the liquid, and the resultant E.M.F. depends on all of these.[1]

In this simple case the energy of the cell is obtained from the passing of the zinc ions from the saturation pressure of the zinc to the osmotic pressure of the liquid, and we obtain at once Nernst's expression for the electromotive force, varying as RT $\log_e P/p$, where P is the saturation pressure, $p$ the osmotic pressure.

But an article which started as a notice of Mr. Jones' most useful book is in danger of becoming a dissertation on the seat of the electromotive force of a voltaic cell, a result to be avoided.

R. T. G.

## MESOZOA AND ENANTIOZOA.

*Traité de Zoologie Concrète.* T. ii. 1^re^ partie. *Mésozoaires—Spongiaires.* By Yves Delage and Edgard Hérouard. Pp. ix + 244. (Paris : C. Reinwald, 1899.)

AS might have been anticipated, this part of the massive "Traité de Zoologie," which is now in course of publication, contains matter of exceptional interest. One-fifth of the present issue is devoted to the Mesozoa, and the remainder to the Sponges. The Mesozoa are classified provisionally under four divisions:—(1) Mesocœlia for *Salinella*; (2) Mesenchymia for *Trichoplax* and *Treptoplax*; (3) Mesogonia for *Dicyemidae* (parasitic in the renal sacs of dibranchiate Cephalopods) and *Orthonectidae* (parasites of Nemertines, Ophiurids and Polychaets); (4) Mesogastria for *Pemmatodiscus*.

---

[1] A reference should be made to Prof. Lodge's article in the May number of the *Philosophical Magazine*, which has appeared since the above wa written.

*Salinella* has been regarded as the incarnation of an ideal promorph, the true *Mesozoon*, or link between unicellular and multicellular animals. The minute creature which has been saddled with so grave a responsibility was found, in 1892, by the late Dr. Frenzel in a jar of 2 per cent. salt solution containing mud taken from the salt works of Cordoba, in the Argentine Republic. The jar had been exposed for a long time, and some iodine washings had been thrown into it by mistake. The authors of the "Traité" give a full account of *Salinella*, and admit that, if it really exists, "c'est le vrai Mésozoaire."

When the complex character of the structure and life-history of the higher Protozoa is considered, the imputed simplicity of *Salinella* becomes almost grotesque, and it seems impossible to assign a cosmic importance to it, even should its autonomy become, in future years, an established fact.

> "On ne le dit pas, mais il règne une certaine méfiance vis-à-vis de cet être venu si à propos, recueilli dans des conditions si étranges, observé si loin de nous et une seule fois. Ce vase contenant un liquide artificiel, exposé à l'air et aux poussières, qui a reçu les rinçures de la verrerie d'une table d'histologiste, ce pays lointain, tout cela ne prouve rien d'une manière positive contre la Salinelle."

*Trichoplax* and *Treptoplax* are likewise aquarium-products, the former having been found at Trieste, in 1883, by Prof. F. E. Schulze, and the latter at Naples, in 1892, by Prof. F. S. Monticelli. These forms, which superficially resemble an acœlous Turbellarian, are riddles of the aquarium, like *Salinella* in this respect, and it seems premature to draw far-reaching conclusions from them until they are themselves solved.

The authors of the "Traité" introduce new matter into their account of the Mesogonia derived from a work written in Russian by N. A. Keppen, in which the spermatozoa of *Dicyema* are described and figured for the first time. Attention is drawn to the mystery surrounding the dissemination of the Dicyemid parasites from one host to another, since it is only the infusoriform males which can endure immersion in sea-water, this being quickly fatal to the vermiform females.

*Pemmatodiscus* is a gastruliform organism found by Monticelli (1895), living in closed sacs in the jelly of a Medusa, *Rhizostoma pulmo*. It would no doubt have excited enthusiasm twenty years ago. Its right to be regarded as an independent type is founded upon three considerations, namely, its parasitic habit, its inability to endure immersion in sea-water, and its power of multiplying by division. The first and last of these reasons are by no means conclusive, since parasitic larvæ, as well as embryos contained in brood-pouches, are known among Medusæ, as is also the phenomenon of embryonic fission.

An account of Haeckel's Gastræadæ is given on pp. 38 and 39, by way of appendix. One might almost have expected to find that the apocryphal Physemaria would have been allowed to go the way of *Bathybius* and *Eozoon*.

A second appendix (pp. 40–45) is devoted to the ciliated urns found in the body-cavity of Sipunculids. These are regarded by M. M. Kunstler and Gruvel, whose original drawings are here published for the first time, as being certainly parasites, and not forming part of the organisation of the Sipunculid. Two genera are described, *Kunstleria* n.g. from *Phymosoma*; and *Pompholyxia*, Fabre-Domergue, from *Sipunculus*.

In their treatment of the Sponges, the authors tread on firmer ground, and the result of their labours is a most satisfactory performance. As promorph (type morphologique) of the entire group, they select for preliminary description the *Olynthus* of Haeckel. *Olynthus* is a generalised abstraction which has its embodiment in concrete zoology. Admitting that a treatise on Sponges at present could hardly be introduced in any other way, it may be pointed out that there are reasons for doubting whether the phyletic value of the *Olynthus* is as great as its undoubted morphological and didactic importance.

In the section devoted to the calcareous sponges (pp. 66–82), the authors quote freely from the researches of our compatriots, Prof. E. A. Minchin and Mr. G. P. Bidder. The classification recently suggested by Bidder is given *in extenso* on p. 67, although not adopted in the body of the work.

The sextets of actinoblasts which secrete the triradiate spicules of Ascons, as discovered and described by Minchin, are duly recorded, but the figure reproduced on p. 67 gives no idea of the excellence of the illustrations contained in Minchin's monograph.

The complete inversion of the layers, which takes place at the metamorphosis (pp. 60, 69, 106, 159), marks one of the most interesting phases of sponge-life. The primitive endoderm of the larva gives rise to the permanent epidermis of the adult, while the primitive flagellated ectoderm sinks in to form the flagellated chambers of the adult. This fact of inversion has induced Delage to separate the Sponges, under the designation Enantiozoa, from all other Metazoa.

The metamorphosis of the parenchymula-larva is accompanied by phenomena which have an interest extending beyond the limits of sponge-lore. The account given on pp. 110–111 shows the following succession of events which occurs in some cases during the conversion of the flagellated ectoderm of the larva into the choanocytes (collar-cells) of the adult:—

| I. | II. | III. | IV. |
|---|---|---|---|
| Flagellated Ectoderm. | Histolysed Ectoderm. | Syncytial Ectoderm. | Choanocytes. |

The reconstructions on the coloured plates, which elucidate the increasing complexity of the inhalent and exhalent canal systems throughout the group, are well executed, and produce a satisfying impression of solidity and reality. If there is a complaint to be made, it is that, in not a few cases, the authors have omitted to add in brackets the name of the generic type to which the diagrams and text-figures may be taken to refer.

Textual errors and inconsistencies are rare, and obvious when they occur. A few examples will suffice. On pp. 2 and 36, the terms "cœlomique" and "cœlome" refer to a blastocœlic space; on p. 60, "gemmules" is given as an alternative expression to "bourgeons," which arise as outgrowths involving all the layers of the body (*e.g. Lophocalyx*), whereas on p. 177 the endogenous "gemmules" of *Spongilla* are rightly described as special formations, quite distinct from ordinary lateral or exogenous buds, although the buds of *Tethya* (p. 167) seem to be intermediate between the exogenous and endogenous varieties. On p. 91 (footnote), Sollas's term *collenchyme* is branded, with other related terms, as "bien inutile," but on p. 152 the superficial cortex of *Geodia* is characterised as "collenchymateuse."

In a footnote on page 203, we are reminded that H. J. Carter instituted a comparison between the flagellated chambers of sponges and the branchial sac of Ascidians. The authors add that this comparison "nous semble bien singulière aujourd'hui où ces êtres sont mieux connus." On the contrary, the comparison is appropriate, the analogy between the flagellated chambers of a sponge (in respect of their respiratory and nutritive functions and of their relations to the inhalent and exhalent canals) and the branchial sacs of the Ascidiozooids in a compound Tunicary (*cf.* especially the Didemnidæ) being an extraordinarily close one; but of course Carter was innocent of the distinction between homology and homoplasy. What is very singular indeed is the fact that, in these latter days, the same fatal confusion between actual physiological conditions and abstract genetic relationships is constantly being repeated. A. W.

## *THE DURATION OF THE BRITISH COAL-FIELDS.*

*Les Charbons Britanniques et leur épuisement.* By E. Lozé. Pp. ix + 559, and vii + 562 to 1229. (Paris: C. Béranger, 1900.)

IN France, as in the rest of Europe, consumers have during the past winter been complaining of the difficulty of obtaining an adequate supply of coal, the chief cause of the increased demand having been the activity in the iron and steel trades. At the same time, prolonged strikes in Austria and elsewhere, and the temporary cessation of the production of the collieries of Natal and Cape Colony, have lessened the supplies usually available. The prevailing scarcity of coal is a matter of serious moment to France, where, owing to the increasing depth of the collieries and the costly nature of mining operations, the quantity of coal that has to be imported from other countries grows larger every year. At the present time about two-thirds of the coal consumed in France is raised in the country; and last year the imports amounted to 10,500,000 tons, of which quantity 6,000,000 tons were obtained from Great Britain. France being so largely dependent on Great Britain, it will readily be seen that the duration of the British coal-fields is a subject of no little importance to French economists. M. Lozé has, therefore, been induced to devote two bulky volumes, covering together 1229 pages, to a critical consideration of the investigations of Prof. Stanley Jevons, the Right Hon. Leonard H. Courtney, Mr. R. Price-Williams, Mr. T. Forster Brown, Prof. E. Hull and othe English writers.

The results of his studies are grouped in four sections. The first contains an account of the geography of the British Isles, with historic, geological and economic details. The second section contains a detailed description of each of the British coal-fields, with a chapter on the coal resources of the Colonies. The third section deals with commercial geography, water and railway transport, and the principal industrial centres. The fourth and last section contains an estimate of the coal supplies of the United Kingdom, with a summary of the views expressed as to their probable duration. The work concludes with a lengthy appendix dealing with cognate matters, the production and consumption of mineral fuel in various parts of the world, the constitution of the British Colonial empire, the navy and the army.

In discussing the views of the various authorities, the author prefers to accept the pessimistic forecast of Mr. T. Forster Brown rather than the optimistic estimate of Prof. Hull. Mr. Forster Brown calculates that the amount of coal of good quality remaining in the United Kingdom at a depth not exceeding 2000 feet, the depth that he regards as the limit of economical mining, is 15,000 million tons. Such is the supply on which Great Britain must base its hopes in the inevitable economic conflict with the United States. In spite of the care and accuracy with which the divergent views on the subject are set forth, it may be doubted whether the author has made out a clear case for rejecting Prof. Hull's estimates, which show that the amount of coal remaining within a depth of 4000 feet is 81,683 million tons. The criticism of Prof. Hull's views is not convincing, inasmuch as M. Lozé, who does not appear to possess a practical knowledge of geology and mining, has not followed the recent investigations as to the limits at which mining may be carried on with profit. At the present time the greatest depth at which in Great Britain mining operations may be carried on has been reached at the Pendleton colliery, near Manchester, where the deepest workings are nearly 3500 feet below the surface. This enormous depth has, moreover, been exceeded in other countries, notably in the Lake Superior district, where a shaft of the Calumet and Hecla copper mine has now attained the record depth of 4900 feet, and in Belgium, where a colliery at Mons is 3937 feet deep. Depths such as these show that the limit of depth of 4000 feet assumed by Prof. Hull is well within the bounds of possibility. In view of the marvellous efficiency of modern winding-engines, no considerations of a mechanical nature need limit the prospective depth of shafts. By far the most important obstacle to very deep mining is the increase of temperature in proportion to the depth. Here, again, the author is apparently not familiar with recent observations. Since 1848 and 1854, the dates of observations cited by him, methods of determining earth temperatures have been greatly improved, and the results recently obtained at the Paruschowitz borehole in Silesia, put down by the Prussian Government to a depth of 6573 feet, show an increase of temperature of 1° F. for every 62·1 feet. This rate of increase would not present an insuperable obstacle to mining at a depth of 4000 feet.

The author gives in tabular form an estimate of the population, coal output, export and consumption for the years 1899 to 1950, by which date the 15,000 million tons assumed to be now remaining will be exhausted. The prosperity assured by the coal of the country to navigation, manufactures and commerce will then gradually disappear, and the historian of a powerful empire will conclude, the author prophesies, his account of a remarkable period by the words: *Finis Britanniae!* Happily, however, the array of statistics, the copious particulars of the coal-seams, and the faithfully translated estimates of eminent experts do not altogether justify the author's Cassandra-like attitude.

The work has been compiled with great care, and the author deserves high praise for the accuracy with which the names of English places and persons have been presented. On p. 564 there is a curious slip. Speaking of the introduction of railways in 1844, the author says: "Mine, aubergiste *of the George*, pleurait la fin des diligences." The archaic expression "Mine host" has proved too severe a test for the author's undoubtedly extensive knowledge of the English language.

Bennett H. Brough.

## OUR BOOK SHELF.

*Ueber den Bau und die Entwicklung der Linse.* By Dr. Carl Rabl. Pp. 324; plates 14. (Leipzig, 1900.)

In the "Notes" column brief mention has recently been made of the concluding portion of Dr. Rabl's important investigations on the structure and development of the crystalline lens of the eye, which appeared in the *Zeitscrhift fur wiss. Zoologie.* The author has now reproduced the entire monograph as a separate work, with the original coloured plates; and since it is a most elaborate treatise on a very difficult subject, its appearance in this form should be welcomed by all students of this branch of anatomy.

There are, perhaps, few phenomena in the developmental history of animals more astounding to the ordinary mind than the fact that a structure seated so comparatively deep as is the crystalline lens of the human eye should arise from the outer, or epiblastic, layer of the embryo, and attain its permanent position, first by invagination, and then by separation from its parent layer. Nevertheless, it is a fact about which there can be no possibility of dispute; and the more superficial position occupied by the spherical lens of fishes serves, in a measure, to indicate the manner in which the conditions obtaining in the mammalian eye have been gradually evolved.

By means of the beautiful series of plates illustrating Dr. Rabl's work the student is enabled to comprehend at a glance, firstly, the mode of development of the lens respectively characteristic of fishes, amphibians, reptiles, birds and mammals; and, secondly, the different histological peculiarities presented by the lens itself in the same groups. Within the limits of a notice in this column, it is out of the question to discuss any details of the work before us; but it may be mentioned that in the concluding section the author enters into the abstruse speculation as to what may have been the degree of development of the eye in *Archaeopteryx* and other extinct animals, and also as to the gradations which may have formerly existed between the present differentiated types of lens-structure. Very interesting, too, are his observations with regard to the lens in the aborted eye of the mole. Here the rudimentary condition of the lens does not commence in the course of development, or in the fully adult animal; but it is distinctly observable in the earliest stages, when it is relatively smaller and contains fewer cells than in other mammals. Hence we have evidence of the extreme antiquity of the mole's adaptation to its present state of existence—evidence fully supported by palæontological facts.

The work may be characterised as a masterpiece of patient and careful investigation in an abstruse and difficult line of research.

R. L.

*Building Construction for Beginners.* By J. W. Riley. Pp. vi + 255. (London: Macmillan and Co., Ltd., 1899.)

This is an addition to the increasing number of works on Elementary Building Construction, which all have for their ultimate goal the preparation of students for the May examinations of the Department of Science and Art.

Commencing with the inevitable introductory remarks on drawing instruments and scales, the student is taken through all the various building trades, and at the end of each are added questions in the form of examination papers which should test the student's knowledge as he advances.

As the author observes, isometric projection is a very valuable means of showing the beginner exactly what is intended, as it gives in one view the plan, elevation and section of the object portrayed. We are glad to see that an extensive use is made of such a form of illustration.

We may also congratulate our author on abstaining from confusing his illustrations by figuring with too many dimensions. Some authors refer with pride to their use of such a system, but as Mr. Riley observes, it is very confusing, and tends by its complication to hinder the very object for which it is introduced.

In a new edition several small slips can be attended to, such, for instance, as the wall-plate surroundings in Fig. 384. The brickwork in this case should be taken up to the underside of the tiles. The "summary" at the end of each trade is an excellent innovation, and the book can be confidently recommended as the best of its class.

*Catalogue of the Fossil Bryozoa in the Department of Geology, British Museum (Natural History). The Cretaceous Bryozoa.* Vol. i. By Dr. J. W. Gregory. Pp. xiv + 457, and plates. (London: Printed by the order of the Trustees, 1899.)

We may congratulate Dr. J. W. Gregory in having completed this volume before he left this country to take up the geological professorship at Melbourne. The value of this, and similar works, is inestimable to palæontologists in all parts of the world. The book itself is naturally a list of hard names; but it is something nowadays to know which is the correct name to apply to any particular fossil, and Dr. Gregory gives as far as possible the synonymy, diagnosis, dimensions and geological distribution of each species. A number of woodcuts in the text and seventeen excellent plates illustrate a great many of the species. We should have been glad of a table of the Cretaceous strata, to inform or remind us of the approximate British equivalents of such divisions as Rhodanian, Campanian, Hauterivian, &c., and also to indicate the sense in which the terms Neocomian and Cenomanian are used.

The volume deals with the various families which are included under the sub-orders Tubulata, Cancellata and Dactylethrata. All these are ranged under the order Cyclostomata, the sub-class Gymnolæmata, the class Ectoprocta and the group Bryozoa. It will be remembered that in the catalogue of recent marine forms in the British Museum, by Busk, that author employed the term Polyzoa instead of Bryozoa. The effort to secure a fixity in zoological nomenclature is one of the trials which beset the path of the worker. Dr. Gregory's carefully prepared catalogue will, we hope, have a permanent value in this respect.

## *LETTERS TO THE EDITOR.*

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### The Kinetic Theory of Planetary Atmospheres.

IN the paper which I communicated to the Royal Society on April 5, I examined the logical conclusions obtained on the hypothesis that the atmosphere of a planet is distributed according to the generalised form of the Boltzmann-Maxwell distribution applicable to a gas in a field of external force, with the further generalisation required to take account of the effects of axial rotation. As regards the effects of the planet's attraction on the distribution of density, the expressions assumed to represent these were of the form now generally accepted by writers on the kinetic theory (*e.g.* Watson and Burbury), and the modifications required in taking account of centrifugal force were investigated by me in 1894, and are in harmony with the conclusions to which Maxwell's investigations tend. In the aforementioned paper I showed how to calculate a superior limit to the rate at which a planet is losing its atmosphere, and obtained the results that helium would be permanently retained at all ordinary temperatures by terrestrial gravitation and vapour of water by the gravitation on Mars; conclusions with which those deduced by Mr. Cook would appear to be identical, so far as I judge from his letter.

The objections which naturally suggest themselves to the mode of treatment in this paper are that the distribution in question is that which would be brought about exclusively as the result of molecular encounters, and of the free paths of the molecules between these encounters; and that it therefore represents the distribution in an atmosphere of uniform temperature. In an actual atmosphere the equilibrium of the lower strata is largely modified by convection currents, so that the adiabatic law, rather than the isothermal law, is applicable. This point I hope to discuss at full length in the second part of the paper; in the meanwhile, it is hardly likely that any one will suggest that helium escapes from our atmosphere because the upper strata are at a *low* temperature, but that it would cease to escape if the upper strata were heated up to the same temperature as the lower ones. The point at issue between Dr. Johnstone Stoney and Mr. Cook and myself appears to be how far the Boltzmann-Maxwell distribution represents what happens in the *upper* strata of the atmosphere. To assert "that in the present state of our knowledge it" (the *a priori* method as Dr. Stoney calls it) "cannot be made to furnish a valid investigation," seems to me tantamount to striking at the very foundations of our kinetic theories of matter. It may be that these theories will not resist such an attack, but the consequences of the onslaught cannot be properly traced, except by making mathematical determinations in the way that I have done. It appears to me to be just in this very problem of planetary atmospheres that the fundamental assumptions of the kinetic theory are least open to objections. Experiments on the relation of diffusion to temperature led Maxwell to abandon the notion that the molecules of a gas behave as elastic spheres and to consider the effects of finite intermolecular forces. So far as I am aware, (1) every attempt at a kinetic explanation of the thermodynamical properties of gases on the latter view involves some assumption which restricts its validity to the limiting case of attentuated gases, where the number of molecules within each other's sphere of influence is a negligible proportion of the whole number, and the duration of an encounter is negligible in comparison with the time of free motion between encounters. On the other hand, (2) it is amply proved by Watson and Burbury that the Boltzmann-Maxwell distribution, if it hold at any instant, will hold at all future instants in the *absence* of molecular encounters. (3) Boltzmann's minimum theorem tells us that if encounters take place at random, the molecules tend towards the distribution in question. (4) We are told on good authority that we must regard the Boltzmann-Maxwell law as a theorem in probability. Now the divergence between actual conditions and the assumptions required under heading (1) gets less and less as we ascend in the atmosphere; (3) gives us reason for believing that the Boltzmann-Maxwell distribution holds at the highest altitudes where encounters not unfrequently take place; (2) shows that the molecules which are projected from these strata and ascend to still greater altitudes without encountering other molecules remain distributed according to the same law; and (4) removes the necessity of taking the size of the element of volume $dxdydz$ into account by telling us that the law represents not merely the number of molecules having given limits of velocity occurring in the element, but also the *probability* of a molecule coming within these limits, and this probability may be as small as we please.

If helium really does escape from our atmosphere, either there must be a fallacy in the assumptions underlying (1), (2), (3), or (4), and this fallacy must affect numerous previous writings on the kinetic theory, or else our preconceived notions as to the relation between temperature and kinetic energy are at fault. With regard to (4), it may be objected that the error-law fails to apply to events of exceptional occurrence, and therefore that we cannot apply it to calculate the probability of a molecule escaping from the atmosphere when the velocity required would represent an abnormal divergence from the mean. This point was carefully considered by me. It appears, however, to be the accepted view that abnormal divergences are excluded because in practice they never occur, not because their occurrence is far more frequent than the error-law would lead us to suppose. If the methods of the kinetic theory should prove to be inapplicable to rarefied gases as well as to dense assemblages of molecules, and they do not altogether agree with experiment for distributions of intermediate density, the position is indeed a serious one. In face of such a possibility, instead of abandoning our mathematical calculations we ought to push them to their ultimate consequences, in order to arrive at a better understanding of the true state of the case. The escape of gases from the atmospheres of planets is a phenomenon probably more directly dependent on the translational kinetic energy of the molecules than any other property of gases. The prevailing doctrine that not only is the mean value of this translational kinetic energy proportional to the absolute temperature, but the conceptions of temperature and kinetic energy are physically identical, has always seemed to me to require closer investigation than it has as yet received, and it may well be that the kinetic theory of planetary atmospheres furnishes one means of putting this doctrine to a test.

Plâs Gwyn, Bangor, May 26. G. H. BRYAN.

### The Severn Bore.

NO one who suffers from scientific curiosity should miss seeing a tidal bore at least once in his life. The locality and conditions under which the Severn Bore can be seen make it an ideal object for a pleasurable excursion. The time to be selected is about twenty-four hours after new or full moon; the largest spring tides should be chosen, if possible, and an occasion when the light permits both evening and morning bore to be seen. They occur at about 7.30 to 9 o'clock, a.m. and p.m. The visits should therefore be either when the days are long or at full moon. During a recent excursion, I stayed at Newnham-on-Severn, below Gloucester. This is about 3 hours 20 minutes from Paddington station, and it is possible to leave this station at 3.15 p.m. and be in time for the evening bore, see the morning bore next day, and be back at Paddington by 2.20 p.m.

On April 29, twelve hours after full moon, I awaited the bore at the south-east corner of Newnham Churchyard. The position is the summit of a cliff situated on the outer bank, and near the centre of the base of a U-shaped bend of the Severn, the limbs of the U being four miles long, and the width between the limbs two miles. The prospect is one of the most pleasing in the South of England; the broad, winding river, emerald pastures abandoned by the wandering channel, miles of rich champagne country, with apple and plum orchards, and the distant range of the Cotswolds. At 6.45 p.m. the bore was sighted as a line of white foam between Aure and Fretherne, rather more than three miles down the river. For a quarter of an hour I watched its march up stream, first wheeling by the left, then advancing up the straight reach, and finally wheeling by the right round the last bend. The wheeling movement is most fascinating to watch. I now hurried down to the ferry, and shoved off the boat into deep water to meet the bore, which was now roaring like a railway train. The water channel was about 200 yards wide; at high water it is double that width. On the sands of the opposite convex, shallow shore the bore discharged itself obliquely as a curling breaker. Against our rocky shore it was a bursting surge. A rise of level was perceptible about ten yards in front of this. In the deep channel we rode easily over a smooth wave. Against the rocky promontory which protects the landing-stage the water surged up violently, then subsided 3 or 4 feet, and surged up again more than once. We now put in behind the shelter of this promontory. At 7.15 p.m. the bore was 300 yards past the ferry, having travelled 3¼ miles, or a little more, in thirty minutes. It was due at the ferry, according to the tide-table, at 7.17 p.m. At 7.21 a steady torrent of water was pouring past the promontory. At 7.29 the torrent was roaring, and the standing waves appeared to be 3 feet high. At 7.44 the waves were smoothed out; the current appeared to be quite as swift, but the greatly increased depth diminishes the surface effect of the rough bottom. The boatmen tell me that the current was "logged" when a bridge was in contemplation, a velocity of 11 knots being registered. Owing to dark clouds and a lurid sunset, I took no photographs. After the passing of the bore there was half an hour's gossip at the ferry, with reminiscences of many bores.

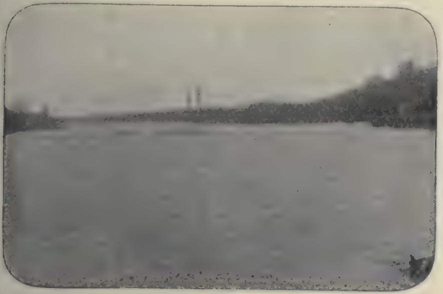

Fig 1.—The Bore approaching.

Next morning, April 30, I got into the dog-cart at 7.30 a.m., and drove 6¼ miles, much of the way through plum orchards in full blossom, to Denny, 9¼ miles by river above Newnham Ferry. Owing to the difference of distance by road and river, it is possible to see the same bore at both places by cycling or driving; but I required spare time to arrange for photography. The clouds were heavy and a little fine rain fell at times, hence the necessarily instantaneous photographs are not as bright as they should be for successful reproduction. The spot for observation is a cottage garden by the Denny Brook. The river here is little more than 50 yards wide, flowing between steep banks, slime-covered between tide marks, with no sandy shoals. The bore appeared at 8.47 a.m., and disappeared round a bend at 8.53 a.m. Taking its time at Newnham Ferry from the tide-table, this gives 70 minutes for time of traversing 9¼ miles, or close on 8 miles an hour. The speed below Newnham was one mile per hour less than this. I guessed the height of the bore at 3 feet in the deep water, 4 feet where bursting on the outer bank. The broken water flew higher than this. These, however, are not trustworthy estimates, as I was busy photographing, obtaining seven exposures in all. Fig. 1 was taken as the bore approached; in Fig. 2 it is seen in passing, showing the wave-surface at back of the bore itself. When in the boat at Newnham I recorded the same thing as a rising and falling of the water against the bank. High water was reached about 9.40 a.m. The current continued to flow up stream; at 10 a.m. it was slack on the concave (western) shore, but still flowing in midstream; at 10.18 a.m. it was distinctly running down even in midstream, the water-level having already fallen nearly 3 feet. From the arrival of the bore to the complete turn of the current may be taken to be 1¼ hours.

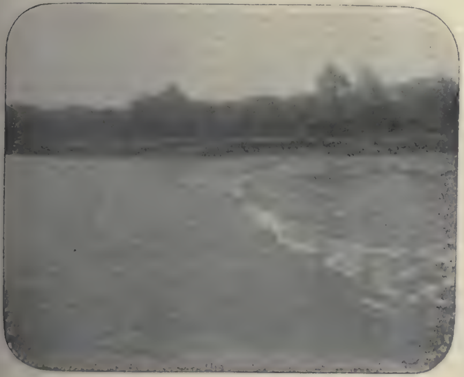

Fig. 2—Wave Surface at Back of Bore.

Ordinary photographs show the form of a bore, but its character does not lie so much in its form as in its motion, which combines the mysterious, ghost-like movement of a wave with the rushing steadiness of a railway train. I hope the phenomenon may soon be cinematographed.

1, Savile Row, W. VAUGHAN CORNISH.

## Bamboo Manna.

THE recent occurrence of a sweet secretion on the stems of bamboos growing in the Central Provinces is a most interesting fact to students of antiquarian medicine. Bamboo manna derives its name from the Sanskrit words—Tvak-kshira, "bark milk"; Vansa-sarkara, "bamboo sugar"; and Vanśa-karpura, "bamboo camphor." Vansa-lochana is the name by which it is known by Indian physicians at the present day. These terms would signify a manna-like substance exuding from the stem of the tree, but what is known and used as Vansa-lochana all over India is quite a different article.

That bamboo manna is not a sugar, but a white, gritty body, now called Tabáshir by Europeans, is gathered from the account of Dioscorides, and from the fact that no kind of sugar prepared from the sugar cane answering to this description was known in India in his time. Dioscorides writes: "What is called *σάκχαρον* is a kind of concrete honey, found in reeds in India and Arabia Felix, in consistence like salt, and brittle between the teeth like salt." Tabáshir, or bamboo manna, was known to the early Arab travellers in the East, and the port of Thana, on the western coast of India, was famous for this product in the twelfth century. Tabáshir is employed as a medicine for its cooling, tonic, aphrodisiac and pectoral properties. In its crude state, when taken from the inside of the bamboo stems, it is mixed with insect remains, and has a blackish appearance; but on gently calcining it becomes quite white, with a pearly lustre. It consists of about 80 per cent. of pure silica, with variable proportions of alkalis, water and organic matter. The history and properties of tabáshir have been very fully discussed by Sir David Brewster (*Philos. Trans.* 1819; *Edin. Journ. Science*, vol. viii. p. 286); Sir George Birdwood (*Bombay Products*, pp. 95–96); Dr. F. A. Flückiger (*Zeit. des Allg. Osterr. Apoth. Ver.* 1887, No. 14), and by Sir D. Brandis (*Indian Forester*, March 1887).

The only modern work which alludes to a sugar in the bamboo is the "System of Botany," by La Maout and Decaisne. The authors remark:—"The young shoots of these two trees (*Bambusa arundinacea* and *B. verticellata*) contain a sugary pith which the Indians seek eagerly; when they have acquired more solidity, a liquid flows spontaneously from their nodes, and is converted by the action of the sun into drops of true sugar. The internodes of the stem often contain silicious concretions, of an opaline nature, named tabáshir." Here a distinction is made between the manna forming on the outside of the stem and the tabáshir found inside, but no reference is made to any record where the first named exudation was observed or examined. Dr Watt, when writing the article on Bambusa for his "Dictionary of Economic Products of India," sums up the general experience with regard to this point, and says: "nor has the spontaneous excretion of sugar on the outside of the stem ever been recorded by Indian travellers."

The strange appearance of manna on the stems of the bamboo was reported last March by the Divisional Forest Officer, Chanda, Central Provinces, and notices of this phenomenon have been published in the local papers. The bamboo forests of Chanda consist of *Dendrocalamus strictus*, the male bamboo, a bushy plant from 20 to 30 feet in height, and affecting the cooler northerly and westerly slopes of Central and Southern India. This is said to be the first time in the history of these forests that a sweet and gummy substance has been known to exude from the trees. The gum has been exuding in some abundance, and it has been found very palatable to the natives in the neighbourhood, who have been consuming it as a food. The occurrence of the manna at this season is all the more remarkable, since the greatest famine India has known is this year visiting the country, and the districts where the scarcity is most keenly felt are in the Central Provinces.

An authentic specimen of this bamboo manna was sent to Dr. Watt, Reporter on Economic Products, Calcutta, and was subsequently handed to me for examination. It occurred in short stalactiform rods about an inch long, white or light brown in colour, more or less cylindrical in shape, but flattened or grooved on one side where the tear had adhered to the stem. It was pleasantly sweet, without the peculiar mawkish taste of Sicilian manna (*Fraxinus rotundifolia*). It was soluble in less than its own weight of water, and the solution when allowed to repose deposited white, transparent crystals of sugar. The manna contained 2·66 per cent. of moisture, 0·96 per cent. of ash, 0·75 per cent. of a substance reducing Fehling solution, and a small quantity of nitrogenous matter. The remainder consisted of a sugar which became inverted in twenty minutes when boiled with dilute hydrochloric acid (1 per cent.), and from its solubility, melting-point and crystalline nature, appeared to be a saccharose, related to, if not identical with, cane sugar. It contained no mannite, the saccharine principle peculiar to true manna.

The bamboos and sugar canes belong to the same natural order of grasses, and perhaps it is not unnatural to expect them to yield a similar sweet substance which can be used as a food; but it is a coincidence that the culms of the bamboo, hitherto regarded as dry and barren, should in a time of great scarcity afford sustenance for a famine-stricken people.

Indian Museum, Calcutta, May 3. DAVID HOOPER.

### Solution Theory Applied to Molten Iron and Steel.

I AM pleased to notice that the theory of solution of iron and steel has recently received attention, and that valuable work has been placed before us for consideration by Baron von Juptner (see recent proceedings of the Iron and Steel Institute).

Will you, however, permit me to state that many years ago, in a contribution to the Institute (*Iron and Steel Inst.* 1881), I advocated the theory of solution in the following words:—

"The solution theory is directly applicable to fluid iron and steel, as it is to water. Carbon, phosphorus, &c., are more or less soluble in the fluid metal, just as salts are soluble in water; in both cases the same forces are at work; water, however, at the normal temperature of 60° Fahr., fluid iron about 2500°–3500° Fahr."

"Further, the physical or gaseous theory of solution best explains the facts; the so-called chemical theory of solution is not so applicable. It is difficult to give satisfactory reasons for the union of stable bodies such as carbon and iron, but the gaseous theory of solution apparently does so.

"The difficulty of its complete or further application becomes one of degree only, for no definite distinction can be drawn between gases, liquids and solids, more especially when the latter are heated.

"The quantity of matter dissolved in a given time is simply a function of temperature, and at low osmotic pressure is comparable with that of a liquid evaporating under the pressure of its own vapour" (NATURE, 1892).

"Moreover, it is remarked that ordinary soft steels for sheets, rails, &c., should be so manipulated as to produce a colloid, or, as near as possible, a non-crystalline material, avoiding always the formation of large crystals" (*Iron and Steel Inst.* 1881).

In my practice I have always adhered to the solution theory, finding that it gave the key to the solution of many discrepancies observed in the manufacture of steel, which ordinary analysis, and the usual theoretical deductions therefrom, sometimes failed to explain.

It appears to me, however, that the solution theory requires extension. We have, I think, up to the present only touched upon the surface of the matter, and more extended and deeper research will amply repay those who have already done work in this direction.

In connection with this subject, although perhaps not exactly bearing upon it, there is what may be termed the theory of the crystallisation of steel and iron. A sheet of ice, as is well known, shows, when heated, beautiful structural, or more correctly crystalline, changes. Why should not a steel plate exhibit changes of this kind if similarly treated?

It is evident, as has been remarked of others, that if the sheet of either ice or iron be suddenly cooled at a given temperature, the structure or grain at that temperature will be approximately retained, and that steel of a given chemical composition may give a material of varying physical properties practically governed by the applied temperature, but not, strictly speaking, in accordance with its chemical composition, as usually assumed.

I have lately found that this happens, and have produced steel of four degrees of hardness by mere temperature manipulation, with metal containing only one-tenth per cent. of carbon together with low per cents. of sulphur and phosphorus. I believe also that this has been done to a certain extent by others, but the facts have not, so far as I know, met with the attention of the practical manufacturers of steel.

Newport, Mon., May 16. JOHN PARRY.

---

## *THE BACTERIAL TREATMENT OF SEWAGE.*

THE discovery made by Schwann, in 1839, that a putrefying liquid swarmed with microscopic living organisms, gave occasion to a long series of remarkable investigations as to the general nature and the life-history of these organisms, and the chemical changes which they produced.

Prominent amongst the names of those who prosecuted these investigations stands that of Pasteur, who, in 1857, drew attention to the nature and causes of fermentative changes produced upon sugar solution, of the putrefactive changes in liquids containing animal substances, and of disease changes in the blood of the living animal, which were produced in the presence of various minute living organisms. He showed that, if these liquids were sterilised by heat, and were then duly protected against receiving solid particles from the air, or from other sources, these changes did not occur; and that contact with air which had passed through a red-hot tube, or had been filtered through a cotton-wool plug, was incompetent to introduce the organisms and to start the above changes.

These researches drew attention to the important part played by the air as a vehicle of the organisms or of their spores, and was supplemented by the researches of Tyndall (1876), who proved that air which had been allowed to remain at rest until its motes had subsided was incompetent to produce putrefaction. Tyndall also proved that boiled sterilised broth, when opened in Alpine air, did not usually putrefy, and that the air near the earth's surface in different localities, and even in the same locality at different times, possessed infective power varying from nil to something considerable. The inference is that the distribution of these organisms and of their spores varies very considerably in any horizontal plane near the earth's surface.

Percy Frankland (1886) determined the number of these living organisms which could be developed from equal volumes of air collected at varying heights from the earth's surface. He made use of hills and cathedral towers for the purpose of collecting his samples, and noted a regular decrease in the number of the organisms which were in the air at greater and greater distances from the earth's surface.

These typical researches render it evident that the organisms and their spores, which are produced at or near the earth's surface, are wafted by natural atmospheric movements to some height, but are constantly tending to subside, and to sow the organisms broadcast as they descend.

It has been shown by more recent bacteriological investigations that many of these minute organisms are normally present in the living organism, and make their appearance in large numbers in the dejecta. It is therefore not remarkable that sewage, which contains the dejecta of men and animals, as well as the washings of considerable road and other surfaces, should contain micro-organisms and their spores in large number.

The fact that animal dejecta and sewage are inoffensively and gradually resolved into simple chemical compounds by contact with different kinds of soil has long been known, but this resolution has, until recently, been attributed to the purifying action of the earth itself, or of the organisms which it may contain. It is now abundantly proved that the resolving or purifying agents are, in the main, the micro-organisms which were originally present in the dejecta themselves, although undoubtedly organisms derived from the air, and those already present in the soil, contribute to the change when they are present.

The experimental purification of sewage by letting it stand in tanks filled with flints, gravel, coal, coke or other mineral substances, proves that there is no special virtue in soil. These experiments, originally commenced by the Massachusetts Board of Health, in 1887, have been repeated by many public sanitary authorities, and their results have been abundantly verified; and in various localities broken stone, broken slate, broken clay vessels, "ballast" or burnt clay have been successfully employed in the tanks in place of the materials which were originally used.

For the successful and inoffensive treatment of sewage by this means, a preliminary "priming" of the material is necessary. This is effected by allowing it to remain immersed in sewage for several hours daily for a few weeks. Sewage, which is then introduced and allowed to remain for a few hours in the tank containing the "primed" coke or other material, has the amount of its putrescible dissolved matters considerably and rapidly reduced, while its solid, finely-divided fæcal matter is brought into solution, and caused to undergo, in large measure, inoffensive resolution into simple compounds.

In order that these changes may be completed inoffensively, it is necessary that the "primed" coke surfaces shall be frequently placed in contact with air, and the process is therefore an intermittent one. The coke-bed is first filled with sewage, which is then allowed to flow out from the bottom and to draw air into the interstices of the coke. After the coke surfaces have been for several hours in contact with the air, the cycle of processes is then repeated. The treatment of fresh quantities of sewage in the same coke-bed may apparently be continued indefinitely.

The effluent from one coke-bed undergoes a considerable further purification if it is made to undergo similar treatment in a second coke-bed; and if this second contact with the coke surfaces is followed by ordinary sand filtration, such as is usually applied to river-water which is to be used for drinking purposes, an effluent of extraordinary purity is obtained.

The original methods introduced by the Massachusetts experiments, and known as the intermittent aërobic treatment, is sometimes preceded by a preliminary anaërobic treatment. This consists in allowing the sewage to remain quiescent in, or to flow very slowly through, a large tank or channel. A thick, tough scum soon forms upon its surface, and protects the liquid from the air. Under these conditions many of the solid suspended particles of an organic nature pass into solution, and are thus rendered rapidly resolvable by subsequent aërobic intermittent treatment.

The above general description of the bacterial treatment of sewage has been subjected to modification as to details to suit the conditions of particular localities. Thus the sewage is in some places subdivided by suitable mechanical arrangements into drops, and allowed to fall continuously like rain upon the surface of the coke-bed. The bed never becomes full of liquid, since when the sewage has trickled through the coke, and has been exposed to the coke surfaces and to the interstitial air, it is at once allowed to flow away from the bottom of the bed.

That these methods of purifying sewage are correctly described as bacterial has been placed beyond doubt. Any conditions which are unfavourable to bacterial life at once retard the purification, while any treatment of the sewage which sterilises it arrests the purification entirely.

The bacteria in the sewage are considered to be the active agents, producing the changes either directly or indirectly through their products or enzymes. Bacteria and their spores are found to be present in great numbers in sewage. London sewage has been shown by Dr. Houston and others to contain very large numbers of bacteria, varying from about three to six million per cubic centimetre. It seems probable that many of these bacteria form films, or "swarming islands," on the coke surfaces, similar to those which are produced by their growth upon the surface of a gelatine film (Fig. 1); the period of formation of these films may be assumed to be the period of "priming" already referred to. Probably the coke-bed aids bacterial action largely by furnishing surfaces of attachment to the bacteria, upon which they may alternately be exposed to air and to the sewage. The useful effect of solid surfaces in promoting bacterial action in the case of other similar changes is well-known, and it may be connected with the effect which the surfaces exert in preventing the settling of the bacteria to the bottom of the liquid.

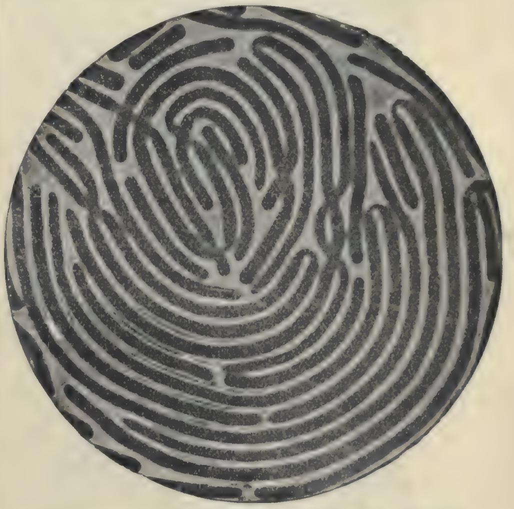

FIG. 1.—*Proteus vulgaris.* Impression preparation from "swarming islands" on gelatine; 20 hours' growth at 20° C. × 3000. (Houston.)

Sewage contains many different species of bacteria, some of which have been described and figured by Dr. Houston.[1] As is seen in Figs. 2, 3, 4, some of these bacteria possess motile tail-like flagella, and by the movement of these the minute organisms maintain a rapid progress through the liquid. Bacteria which are devoid of flagella, and cannot traverse free paths in the liquid, are shown in Figs. 5, 6, 7 and 8. In Fig. 9, the spores of these minute vegetable organisms are seen interspersed amongst the organisms themselves. The organisms have two methods of multiplying, by fission and by producing spores: the spores have great power of retaining vitality. It is found that none of these bacteria are selectively retained by a coarse coke-bed during the treatment, but that all the species make their appearance in but slightly diminished numbers in the purified effluent from the coke-bed. The average reduction in number of bacteria suffered by the sewage by one treatment in a coarse coke-bed amounted to only 27·7 per cent. It would therefore appear that the different species of bacteria assist one another in the purifying action, and by producing either contemporaneous or consecutive effects upon the sewage secure its purification: in bacteriological language, their action is either symbiotic or metabiotic, or possibly of both kinds. The organisms seem to establish and maintain a condition of equilibrium amongst themselves in the coke-bed, since attempts to artificially increase the number of certain species have thus far failed.

---

[1] The illustrative figures in this article have been selected from Reports on "The Bacteriology of London Crude Sewage" and on "The Bacterial Treatment of Crude Sewage." by Dr. Clowes and Dr. Houston, issued by the London County Council (F. S. King and Son); they were originally produced from micro-photographs taken by Dr. Norman from Dr. Houston's cultivations.

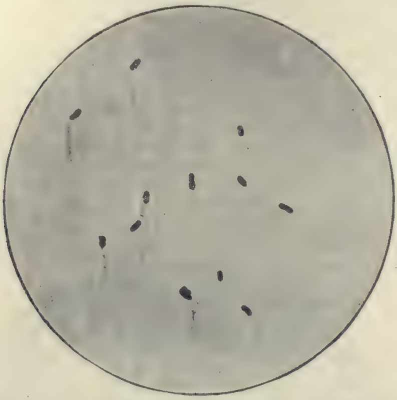

FIG. 2.—"Sewage proteus." Microscopic preparation stained by V. Ermengem's method, showing one flagellum at the end of each rod; from a 24 hours' growth agar culture at 20° C. × 1000.

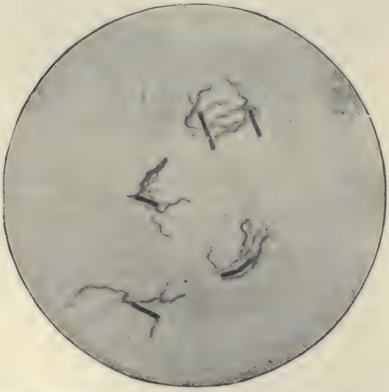

FIG. 3.—*B. mesentericus.* Sewage variety E. Microscopic preparation stained by V. Ermengem's method, showing numerous flagella, from a 20 hours' agar culture at 20° C. × 1000.

It appears that in the above processes there is no separation of the bacterial action which takes place in the presence of air from that which occurs only in the absence of air, and both processes probably proceed side by side in the open coke-bed. The anaërobic, or so-called "septic," treatment, during which cellulose is slowly resolved with separation of hydrogen and methane, is, however, sometimes made to precede the more truly aërobic treatment.

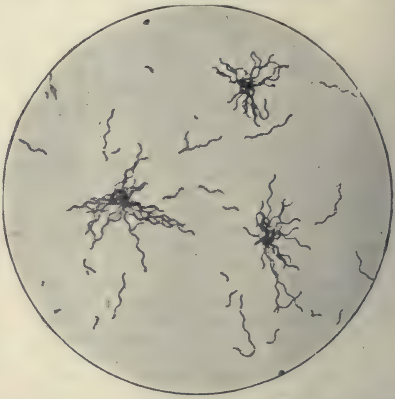

FIG. 4.—*B. mesentericus.* Sewage variety I. Microscopic preparation stained by V. Ermengem's method, showing numerous flagella; from a 20 hours' agar culture at 20° C. × 1000.

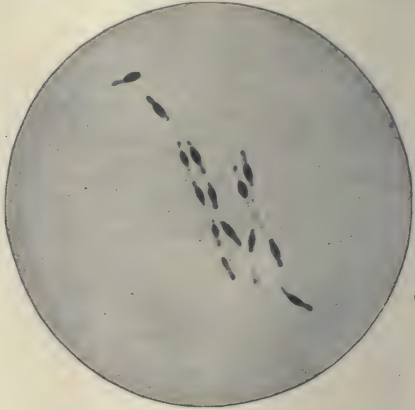

FIG. 5.—*Bacillus subtilis.* × 1500.

One result of the anaërobic treatment is the liberation of large volumes of combustible gas, and this gas has been employed at some works for illuminating purposes on the incandescent principle.

The general products from both processes of bacterial action are carbon dioxide, water, ammonia, nitrogen, hydrogen and methane; and in the aërobic changes the ammonia is subsequently oxidised into nitrite and nitrate.

The experience obtained from several years' experimental bacterial treatment of sewage at several of our largest cities has recently been published.

In 1893 the London County Council constructed an acre coke-bed about three feet in depth at the Barking Outfall of the North London Sewage. This bed has been receiving screened and sedimented sewage up to the present time, the process of sedimentation having been assisted by the addition of a small proportion of solutions of lime and of ferrous sulphate. Two years ago the bed was deepened to about six feet. Its purifying action, as measured by the amount of oxidisable matter present in the raw sewage and in the clear effluent, amounts to 92 per cent., and if the purification is calculated from the clear sewage and effluent, it amounts to 84 per cent. More recent experiments have proved that the treatment of raw, roughly-screened sewage in such coke-beds is satisfactory, but that the capacity of the bed becomes continuously reduced by the deposition upon the coke of mineral matter from road detritus, of particles of straw, chaff and woody matter from the horse-traffic and from the wood pavements. It was, therefore, evident that these matters must be deposited by sedimentation before the sewage was brought into the coke-beds. A comparatively rapid process of sedimentation suffices to remove these matters, since even the cellulose matters arrive in the sewage in a heavy and waterlogged condition.

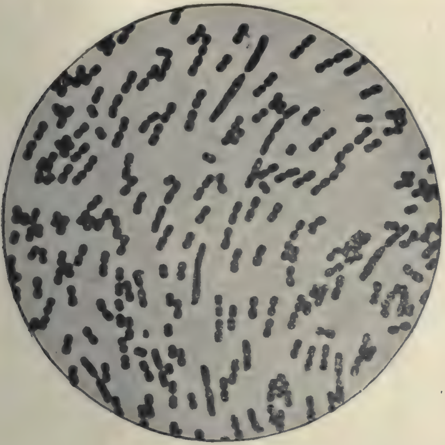

FIG. 6.—*B. subtilissmus.* Impression preparation from a gelatine plate culture. × 1000.

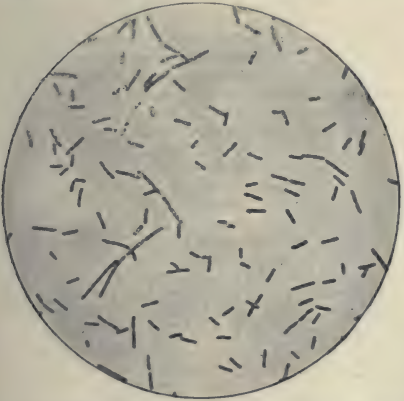

FIG. 7.—*B. mesentericus.* Sewage variety E. Microscopic preparation from a 20 hours' agar culture at 20° C. × 1000.

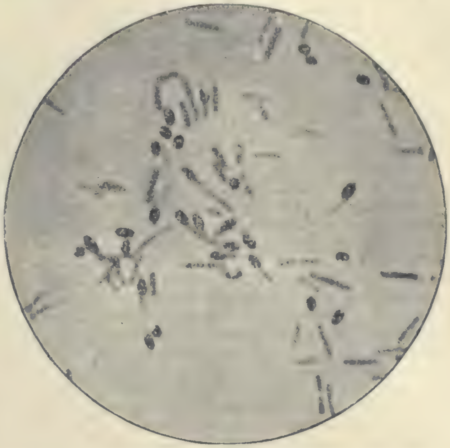

FIG. 8.—*B. enteritidis sporogenes* (Klein). Microscopic double-stained preparation, from a serum culture, showing spores. × 2000.

It was found advantageous to use coke in comparatively large fragments, about the size of walnuts, since this facilitated the rapid draining of the liquid from the coke, and at the same time increased the sewage capacity of the bed and promoted its efficient aëration. The depth of the beds has been augmented from 4 to 13 feet, and the increase of depth seems to be attended with increase of efficiency. The 13-foot bed has for long periods given a purification from dissolved oxidisable matter of over

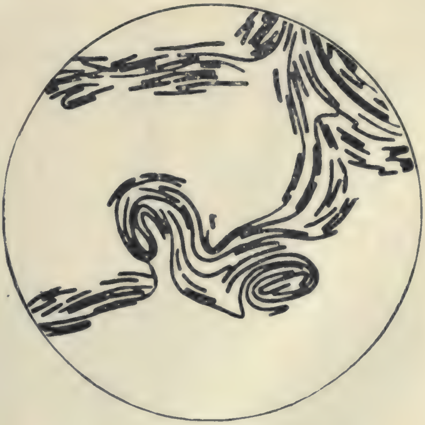

FIG. 9.—*Proteus vulgaris.* × 1000.

60 per cent. It has maintained a most satisfactory state of aëration, since the air drawn from the bottom has contained, on an average, 17 per cent. of oxygen.

About 60 per cent. of the matter which settles from the sewage under ordinary conditions is combustible, and could, therefore, very well be dealt with by a destructor.

The tendency of the coke bacteria beds is undoubtedly to improve in their purifying power with age, provided they are not overworked. A bed which had given for some time a 50 per cent. purification, gradually increased in efficiency until its purifying effect reached nearly 70 per cent. The effluent from this bed underwent an additional purification of 20 per cent. by treatment in a second similar bed.

The effluent from a single coke-bed worked on the intermittent principle was clear and odourless, and remained in this condition when it was kept in open or closed bottles in a warm laboratory. It maintained the life of gold-fish, roach, dace and pike indefinitely: it was therefore not only well aërated, but was able to maintain its aërated condition. This proves that it was free from any rapidly oxidisable matter. It was undoubtedly, however, undergoing gradually further purification by the action of the bacteria which it contained, and with the assistance of dissolved oxygen. Such an effluent would be quite suitable for introduction into the tidal part of the river, where the water is too salt and muddy to be used for drinking purposes.

Bacteria are present in large numbers in the river-water itself, and undoubtedly exert a most useful purifying effect upon the water during its flow. The relation between the number present in the sewage and in the water of the River Thames, below and above locks, is shown by the following estimations made by Dr. Houston. The number of liquefying bacteria included in the total number of bacteria present in one cubic centimetre, and the number of spores of bacteria, are also stated:—

| | Bacteria. | Liquefying bacteria. | Spores. |
|---|---|---|---|
| Raw sewage from North London, Feb. to April 1898 ... ... | 3,899,259 | 430,750 | 332 |
| Raw sewage from South London, Feb. to April 1898 ... ... | 3,526,667 | 400,000 | 365 |
| May to Aug. 1898 ... ... | 6,140,000 | 860,000 | 407 |
| Effluent from coke-bed, South London, May to Aug. 1898 ... | 4,437,500 | 762,500 | 252 |
| [Percentage reduction by passing through coke-bed... | [27·7] | [11·4] | [38] |
| Lower Thames water, Greenhithe, half ebb-tide, Oct. 1898... | 10,000 | — | 63 |
| Lower Thames water, Barking, low tide, Nov. 1898 ... ... | 34,400 | — | 89 |
| Upper Thames water, between Sunbury and Hampton, Nov. 1898 ... ... ... ... | 5,100 | — | 56 |
| Upper Thames water, Twickenham, Nov. 1898 ... ... | 3,000 | — | 18 |

The results obtained by the experimental bacterial treatment of sewage at Manchester during the last two or three years bears out generally those which have been obtained in London. The treatment has differed in some details from that adopted in London. The particles of coke constituting the coke-beds have been smaller. The coke-beds have been subjected to a larger number of intermittent fillings per day; and the preliminary treatment in an open anaërobic tank has been carried out with advantageous results. The scientific experts who have suggested and watched the experiments state their conviction that bacterial treatment is the treatment which is most suitable for Manchester sewage, but that in order to secure the most effective purification, the coke-beds must have sufficiently frequent and prolonged periods of rest, and must be fed with sewage as free as possible from suspended matter, and as uniform in quality as may be. Preliminary anaërobic treatment is referred to as the best means of securing uniformity in quality of the sewage, and of adapting it to rapid subsequent aërobic purification. Four fillings in 24 hours have been found suitable, if one day's rest in seven is given to each coke-bed; the number of fillings, however, may exceed this without detriment to the bed or to the character of the effluent.

Town sewage is found to arrive at the outfalls at an almost constant temperature throughout the year. It rarely falls below 13° C. And this temperature not only prevents the possibility of the coke-beds being stopped by the freezing of the sewage, but also secures to the bacteria one condition favourable to their action. When a bed is too freely aërated by the passage of frosty air constantly through the interstices of the coke, this favourable condition is, however, seriously interfered with, and the bed may even become stopped by the freezing of the sewage.

In the more recent experiments carried out in America by the State Board of Health, Massachusetts, the tendency has been to use fine coke, and to allow the effluent from the coke to pass through sand. The passage of the liquid has either been allowed to take place with the outflow widely opened, so that the bed never fills; or the sewage has been allowed to fill the bed and to remain quiescent in contact with the coke for a time, as in the English experiments. The conclusions arrived at seem to be that the degree of purification obtained by the use of fine coke and sand is very satisfactory, but that the volume of sewage dealt with in a given time is smaller than when larger coke fragments are used, and the tendency seems to be to adopt the larger coke in order to expedite the more rapid drainage away of the effluent.

It will be seen from what has already been said that it is well not to speak of this system of treatment as one of filtration. Filtration ordinarily implies a process of mechanical separation of material suspended in a liquid. The fact that the coke-beds only commence their purifying action after they have been "primed" by repeated contact with sewage, and that this purifying action keeps increasing as the bed "matures," is sufficient to show that the action is by no means of a mechanical nature. It would be well, therefore, to speak of it as a process of bacterial treatment, and thus to indicate that the purifying agents are bacteria, which are acting under control, and are placed under conditions favourable to the development of their full activity.

It would be rash to say that the methods of bacterial treatment have as yet reached their most effective state; but it is significant that these methods have secured converts wherever they have received careful and fair trial, and that those are their warmest advocates who have had the widest experience of their working. It is even probable that further improvements will be made in the means of treating sewage bacterially, but it is quite certain that the processes at present in use are able to secure the economical and satisfactory purification of ordinary town sewage.

FRANK CLOWES.

## THE TOTAL ECLIPSE OF THE SUN.

SINCE the first series of telegrams was received announcing successful observations of the total eclipse of the sun on May 28, all the more detailed reports to hand confirm the universal satisfaction of the various parties at the results. As, however, most of the parties having a definite programme arranged to obtain photographic records, complete details cannot be known until the development of the whole of the plates, and in some cases this will not be until the observers return home.

Rough prints from several of the negatives obtained with the prismatic cameras used by Sir Norman Lockyer's party show as great amount of detail as those taken in 1898. From a cursory examination of the negatives few differences appear in the chromospheric spectrum; the "1474" corona ring seems, however, slightly more feeble than before.

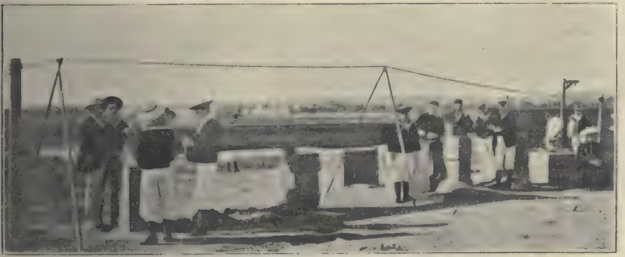

FIG. 1.—Two of the cameras fed by a cœlostat.

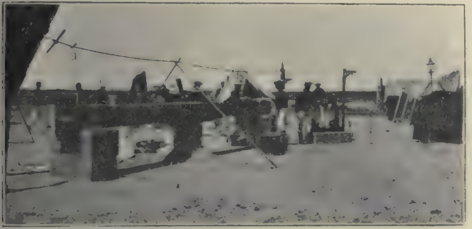

FIG. 2.—The 20-foot prismatic camera and siderostat.

In a letter received from Mr. Fowler he states that the negatives obtained by Mr. Payn with the 16-foot Cooke coronagraph are excellent, especially one showing the inner corona.

The accompanying illustrations, received too late for reproduction with Sir Norman Lockyer's letter last week, show some of the arrangements made for observing the eclipse at Santa Pola. Particulars concerning the various instruments will be found in NATURE of May 17.

Prof. H. H. Turner, at Bonsarea, near Algiers, successfully carried out his programme of photographing the corona, obtaining seven ordinary pictures and seven with interposed polarising apparatus. The polarisation indicated was decidedly radial.

Mr. H. F. Newall obtained the "first flash" and "corona" spectra with both slit spectroscope and objective grating, those taken with the latter, however, being weak. With Mrs. Newall he also made polariscopic observations.

Mr. W. H. Wesley made an excellent drawing from his observations with the eight-inch Coudé equatorial placed at his disposal by M. Trèpied, director of the French observatory at Algiers. He reports that very little structural detail was discernible in the inner corona.

The need for correction of the lunar tables is indicated by the universal experience that totality was some seconds *less* than that previously computed. The American observers estimate the difference as three seconds, while at Ovar, in Portugal, Mr. W. H. M. Christie, the Astronomer Royal, gives the time of totality as 85 seconds, whereas the calculated value was 93 seconds. Several observations indicate that the discrepancy is to be looked for in the moon's diameter being taken too large.

The most unfortunate victim of this error appears to have been Mr. Evershed, who journeyed to an outlying station, near Mazafran, so close to the limiting line of totality as was considered safe. He did this with the object of photographing the "flash" spectrum with as long duration as possible; this will be understood when it is considered that exactly on the central line the duration of the flash will be merely momentary, but as the observer recedes from the central line the line of sight to the moon's limb becomes more oblique, until on the limiting line of totality the so-called "flash" is visible for the whole time of totality at that point. Owing to this ambiguity of the data, the station chosen was evidently somewhat further from the central line than was anticipated, and consequently Mr. Evershed had the unpleasant experience of less than one second totality. His preparations must have been exceedingly perfect, however, for he reports having obtained a good photograph at the proper instant, though it will fall short of expectation for the reason stated.

Prof. Howe, of Denver, has already determined the position of the planet Eros, which he was fortunate enough to discover on his photographic plates during the eclipse, and has circulated his result. The coordinates of the planet will be found in the "Astronomical Column."

C. P. B.

## NOTES.

SIR ARCHIBALD GEIKIE, F.R.S., has been elected a Foreign Honorary Member of the American Academy of Arts and Sciences in the section of Geology, Mineralogy and Physics of the Globe, in succession to the late Carl Friedrich Rammelsberg.

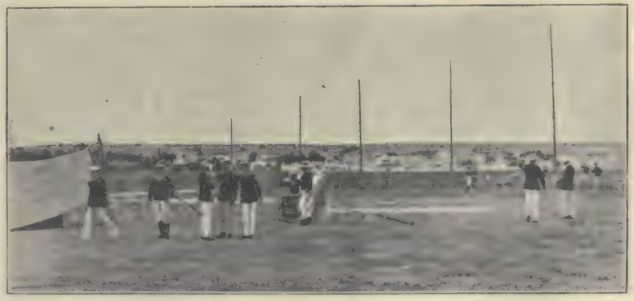

FIG. 3.—Discs on spars, for naked eye observations of the corona.

PROF. FOUQUE has been elected vice-president of the Paris Academy of Sciences for the year 1900, in succession to the late Prof. Milne-Edwards. Prof. Boltzmann has been elected to succeed the late Prof. Beltrami, in the mechanics section of the Academy.

PROF. PAUL GROTH, of Munich, has been elected a Foreign Member of the Geological Society, and Prof. A. Issel, of Genoa, a Foreign Correspondent.

THE annual conversazione of the Institution of Electrical Engineers will be held on Tuesday, June 26, at the Natural History Museum, South Kensington. The guests will be received by the president (Prof. Perry), and Mrs. Perry.

THE Croonian Lectures for 1900 will be delivered by Dr. F. W. Mott, F.R.S., before the Royal College of Physicians of London, on June 19, 21, 26 and 28. The subject is "The Degeneration of the Neurone."

IT is stated that Captain W. Bade di Wismar has organised an expedition to the east coast of Spitsbergen and Franz Josef Land to seek for traces of Andrée, and also to obtain intelligence of the Duke of the Abruzzi. No apprehension is felt about the Duke of the Abruzzi, as a long interruption in his communications with the rest of the world was foreseen.

A MEETING was held at the Meteorological Society on Thursday last to consider the question of a memorial of the late Mr. G. J. Symons, F.R.S. It was resolved that the memorial should take the form of a gold medal, to be awarded from time to time by the council of the Royal Meteorological Society for distinguished work in connection with meteorological science. An executive committee was appointed to take the necessary steps to raise a fund for this purpose. Contributions will be received by the assistant secretary, Mr. W. Marriott.

LORD LISTER will open the new clinical laboratories at the Westminster Hospital on Tuesday, June 12, at 4 p.m. He will be received by Sir J. Wolfe-Barry, chairman of the committee, and supported by Lord Kelvin, Sir Michael Foster, M.P., Dr. Church, president of the Royal College of Physicians, Sir William MacCormac, president of the Royal College of Surgeons, and the Dean of Westminster.

THE completion of the twenty-fifth year of teaching by Prof. Luciani, Rector of the University of Rome, was celebrated on May 3 in the physiological laboratory of the University. The *British Medical Journal* states that the theatre was crowded with admirers of the well-known physiologist, conspicuous among whom was Prof. Baccelli. An address was delivered by Prof. Todaro, to which Prof. Luciani, who was much moved, replied. Prof. Baccelli also spoke, and ended by embracing Prof. Luciani, who was the object of enthusiastic congratulations from the assembly.

THE decision of the Trinity House authorities to remove the wireless telegraphy installation between the South Goodwin lightship and the South Foreland was discussed by the Dover Chamber of Commerce on Friday. It was decided to memorialise the Trinity Board and to request the Chambers of Commerce of the ports of the United Kingdom, as well as Lloyd's and other shipping bodies, to support the memorial, with a view to the establishment of a connection between lightships and the shore on dangerous sands.

THE president of the Board of Education has approved of a Committee, which is now sitting, "to inquire into the organisation and staff of the Geological Survey and Museum of Practical Geology; to report on the progress of the Survey since 1881; to suggest the changes in staff and arrangements necessary for bringing the Survey in its more general features to a speedy and satisfactory termination, having regard especially to its economic importance; and, further, to report on the desirability, or otherwise, of transferring the Survey to another public department." The members of the Committee are:—The Right Hon. J. L. Wharton, M.P. (chairman), Mr. Stephen E. Spring Rice, C.B., Mr. T. H. Elliott, C.B., General Festing, C.B., Dr. H. F. Parsons, Mr. W. T. Blanford, F.R.S., and Prof. C. Lapworth, F.R.S., with Mr. A. E. Cooper as secretary.

THE announcement of the death of Miss Mary H. Kingsley, at Simonstown, on Friday, will be received with deep regret by geographers, ethnologists, and many others who are familiar with her works. Miss Kingsley was the elder of the two children of the late Dr. G. H. Kingsley, and quite recently (May 3) her memoir of her father, published with his "Notes on Sport and Travel," was noticed in these columns. Miss Kingsley will chiefly be remembered for her explorations in West Africa, and her works upon them. The first volume in which she recorded her experiences was "Travels in West Africa," published in 1897. Last year, a further volume of "West African Studies" appeared, and a few weeks ago her "Story of West Africa" was published in the Empire Series. Miss Kingsley's books are marked by a sincerity and humour which make them of deep interest even to readers who may not always agree with her forcibly-expressed convictions. Her interest in West Africa, as an obituary notice in the *Times* points out, was partly scientific, partly sociological, partly political. She made numerous contributions to our knowledge of the fishes of some of the West African rivers, and of the reptiles in that part of the continent. In both her books on West Africa she made valuable additions to our knowledge of the native mind and character, and her studies in fetish bring out in a remarkable manner the sympathetic insight which enabled her to project herself into the mind of the negro races. In "West African Studies" Miss Kingsley set forth, with much array of facts and arguments, a strong indictment of the system of government by Crown colonies in West Africa. Personally, Miss Kingsley was of a modest and retiring disposition; but the frequent journeys that she made up African rivers and through the bush with none but native attendants afforded undoubted testimony to her pluck, powers of endurance and fertility of resource.

AT the last meeting of the General Medical Council, the report of the Pharmacopœia Committee, referring to the subject of a proposed international Pharmacopœia limited to drugs of a drastic nature, was adopted. If an international conference on the subject in question is arranged, the Council will appoint representatives to participate in it, and one or more members will be appointed to act as delegates. Communications have been opened with the United States authorities with a view to bringing about greater uniformity in the official preparations contained in the British Pharmacopœia and the United States Pharmacopœia respectively; and it is hoped that, by mutual concessions, important approximations and assimilations in the contents of the two works may be ultimately secured. Further communications have been received with reference to the Indian and Colonial "Addendum," and important suggestions from Canada have been considered by the committee in detail. It is hoped that the addendum will be authorised for issue by the end of the year. By the efforts of Dr. Leech, a valuable collection of British and foreign works bearing on the history and development of the Pharmacopœia has been collected and deposited in the office of the Council.

THE widespread invasion and persistent devastations of locusts in so many parts of Africa give interest to all trials and experiments, as well as the ordinary remedies, employed for the alleviation of this ruinous plague of the farmer. The following notes from Mr. W. C. Robbins, Stock Inspector of the Lower Tugela and Mapumulo Districts, are published in the Cape official *Agricultural Journal*:—"For the past three days I have been over the ground where my men have been infecting locusts with Government fungus, and the result was that I found dead locusts everywhere. I send you a sample; you will notice they are full of worms, and we know from experience than when locusts are found in this state whole swarms die off. Some, you will see, are half eaten; these were eaten by their fellows. I have seen many clusters of locusts eating dead ones." The feeding upon bodies of dead locusts suggests that diseased locusts may be utilised as a substitute for locust fungus. Tests are being made to determine whether a preparation from diseased dead locusts will infect a swarm in the same way as locust fungus made in the Government laboratory.

IN a paper on "The Standardisation of Electrical Engineering Plant," published in the *Journal* of the Institution of Electrical Engineers, Mr. R. Percy Sellon arrives at the following general conclusions:—(*a*) Standardisation to a greater degree than at present exists is in the interest of the manufacturer, as a means of facilitating repetition and production, and of meeting the competition of standardising foreign manufacturers. (*b*) Standardisation of "ends" or "performance" as distinct from "means" or "constructional details" is equally in the interest of the user, by securing for him low purchase cost, prompt delivery, freedom from the risks of experimental designs, and full manufacturers' guarantees. (*c*) The relative absence of standardisation in Great Britain, in contrast with other countries, is mainly traceable to the prevailing system wherein the user's engineer specifies "means" or "constructional" details instead of confining himself to "ends" or "performance." (*d*) The determination of standards by organised effort rather than by the slow and costly process of "trial and error" is desirable, and should be undertaken under the auspices of the Institution of Electrical Engineers, as representing the interests of both producer and user.

IF standardisation is important for the electrical engineer, it is none the less urgently needed in connection with scientific literature. Although the pages of a large number of journals and transactions, both in this country and on the Continent, are of uniform sizes, both quarto and octavo, this is by no means the universal rule; and proceedings, especially of local societies in remote districts, as well as the more popular class of scientific journals, show almost every possible variation in the dimensions of their pages. We have before us a pile of such publications, arranged in order of size, and increasing gradually from 7 × 4½ inches at the top to 12 × 10 inches at the bottom. They include many papers which it is desirable to bind up with other literature on the same subjects, but which have had to be relegated to "the pile" on account of their inconvenient sizes. This is the more unfortunate because journals of this particular character often contain reports on current research, the inclusion of which in bound volumes of reprints, easy of reference, might often save those repetitions of investigations which involve much loss of time, and only lead to disappointment, accompanied by unpleasant—not to say undignified—controversies as to priority.

THE U.S. Department of Agriculture has issued a Bulletin, No. 74, containing "Organisation Lists of the Agricultural Colleges and Experiment Stations in the United States, with a list of Agricultural Experiment Stations in Foreign Countries." Thirty-six pages are occupied by notes on the courses of study and the names of the boards of instruction at fifty-nine colleges exclusively devoted to agricultural teaching, or with agricultural departments; while twenty-one pages give the names of the governing board and staff at fifty-six experiment stations. Then follows a list of foreign experiment stations, with the names of the directors, to which is added a most useful statement of the more important publications issued in 1899 by the various stations of the United States. Some notes on the relationship of the colleges and stations to the United States Treasury complete this exhaustive record. Probably, the information, so far as it concerns the United States, is trustworthy, but the same cannot be said in regard to the British stations, for this section of the work is defective alike as regards accuracy and completeness. It would be well to have the British section thoroughly revised in any future issue.

WE have received from Dr. W. van Bemmelen a memoir on the deviation of the magnetic needle from the end of the fifteenth century to the year 1750, with isogonic charts for the epochs 1500, and subsequent half centuries down to 1700. The work is published as a supplement to vol. xxi. of the "Batavia Meteorological and Magnetical Observations," and is the outcome of researches made during several years in various libraries and archives in the Netherlands and other European countries prior to the author's appointment to the Batavia Observatory. The work is a laborious compilation of all the most trustworthy observations, commencing with the voyage of Columbus in 1492, and is a most valuable contribution to terrestrial magnetism, containing between five and six thousand observations in all parts of the world, with references to the positions and the sources whence the information has been obtained. The value of the work is much enhanced by numerous critical remarks and by explanatory text; the language used is German.

As attention has recently been much directed to the enormous drafts that are being made on the coal supply of the world for power purposes, the following description of one of the most recent attempts to obtain power by utilising the hitherto wasted resources of nature may be of interest. A company called the Saint Lawrence Power Company, composed of English and American shareholders, some time since obtained a tract of 2000 acres of land at Massena, adjacent to the Saint Lawrence and Grasse rivers. On this land an electrical installation of considerable magnitude is in course of construction. The works, which it is expected will be completed next autumn, are intended to develop ultimately 110,000 horse-power. The plant is situated on the River Grasse, a tributary of the Saint Lawrence, from which the water for driving the machinery will be diverted through a canal three miles long, 200 feet wide at the bottom, and 25 feet deep. The bottom of this canal at the river end will be 60 feet above the ordinary water-level in the River Grasse, which will form the tail-race for the turbines. The preliminary mechanical equipment will be eight units of 5000 horse-power, each obtained by three twin turbines and dynamos. The land adjacent to the works which is to be utilised for manufacturing and allied purposes will be accessible by branches of the New York Central Railway and by the canal to the Saint Lawrence, which will be large enough to take vessels of considerable draught.

THE means of overcoming the difference of level of the country through which canals pass is in most cases overcome by locks placed either singly or in flights, depending on the height to be overcome. About twenty-five years ago, the locks between the Trent and Mersey Canal and the River Weaver, where there is a difference of 50 feet, were superseded by the hydraulic lift at Anderton. The boats here are floated into iron troughs which are raised or lowered by hydraulic power, one boat ascending and another descending at the same time. This system was subsequently adopted on other canals in France and Belgium, and, with some modifications, in Germany. What is claimed as an improvement on this system is now being carried out on the Erie Canal in America, at Lockport, by what is termed a "Pneumatic Balance Canal Lock." A description of this lift was given in a paper contributed to the Franklin Institute by Mr. Chauncey N. Dutton. The existing stone locks were erected in 1836, and overcame a lift of 62½ feet by means of five flights. The lock which is being erected to supersede these consists of two steel chambers, one for ascending and the other for descending boats. These chambers are divided into two parts, the upper one containing water to receive the boats, and provided with gates, as in the case of the Anderton lift; and beneath this a second chamber containing compressed air on which the lock-chamber floats. The air-chambers are so proportioned that they automatically differentiate the air-pressure. The water in the lock-chamber which contains the boat at the upper level is so adjusted that its weight, with the boat it contains, is 200 tons greater than that of the lower one. Each of these locks weighs 1500 tons and contains 4500 tons of water, the weight in motion, when the boats are ascending and descending, exceeding 12,000 tons. The advantages claimed by the use of compressed air are a saving in cost, safety in working, and great economy in water. The power for compressing the air is furnished by a 36-inch turbine working a four-cylinder pump. This also drives the dynamos which operate the gates and light the lift.

A RECENT report by Prof. Le Neve Foster upon the number of persons employed, and the number of fatal accidents, in mines and quarries in the United Kingdom, shows that in 1899 the death-rate of the workers at mines under the Coal Mines Act, taking underground and surface workers as a whole, was 1·26, whilst that of 1898 was 1·28. At the mines under the Metalliferous Mines Act, the death-rate of the underground and surface workers as a whole was 1·59, a figure decidedly higher than that of 1898, which was only ·96. The inside workers in quarries had a slightly smaller death-rate from accidents in 1899 than they had in the previous year.

A RECENT consular report (No. 2418) on the trade of Corsica states that of the few industries at present carried on, that of extracting tannic acid from chestnut wood is now perhaps the most flourishing in the island. This industry is carried on in Bastia, which is the commercial centre of Corsica, by two large factories which export together about 4000 tons of extract per annum, in concentrated liquid form. To prepare this quantity requires nearly 20,000 tons of wood of the sweet chestnut tree yearly. The immense forests are equal to supplying the demand for many years; but this tree not being under the control of the Administration of Woods and Forests its wholesale destruction without compulsory replanting will, it is feared, in time not only influence adversely the climate of large districts, but cause much misery in those districts where chestnut flour forms the staple food of the peasants. It is prepared from the dried fruit of the sweet chestnut.

ACCORDING to the Acting British Consul at Samoa, rubber has been introduced there, and is being grown by several of the planters. It appears to thrive, and as far as can be seen the soil is admirably adapted for the growth of this most valuable product.

WE have received the official edition of the Fourth Annual Report of the New York Zoological Society, the substance of which is given in more popular form in a publication alluded to a short time ago in our "Notes" column.

THE Marlborough College Natural History Society, in its *Report* for 1899, sets an admirable example to institutions of this nature in publishing a list of the Lepidoptera of the district, the elaboration of which has been a work of years. It is by the thorough working out of local faunas that provincial natural history societies can alone properly justify their existence.

REFERRING to a remark in the review of the "Vertebrate Fauna of the Shetland Islands" in NATURE of May 24 (p. 75), Mr. Eagle Clarke writes to say that though he revised some of the proofs, the revision of the Cetaceans was undertaken by Mr. James Simpson, and that he did not revise either the MS. or the proof relating to that order. "Mr. Simpson, who had a special knowledge of the group, has passed from among us, but I have little doubt that his inclusion of the Narwhal in the *Physeteridae* was the result of a mere slip."

THE *Entomologist* for June contains the first instalment of the translation of an article by Prof. Max Standfuss on experiments in hybridisation, and on the influence of temperature on the development of the Lepidoptera. As an instance of the line of investigation followed, we may quote the case of the map-butterfly (*Vanessa levana*), in which the difference between insects bred from the summer and winter pupæ is so great as to have formerly led to the belief that they belonged to different species. By placing the summer pupæ in an ice-house the winter imago was produced; but, on the other hand, it was found much more difficult to change by warmth the winter pupæ into the summer imago. This led to the inference that the winter form was the original one; and this is confirmed by the circumstance that the only near relatives of this insect are four species from northern Asia.

THE second edition, revised and largely rewritten, of Dr. Julius Wiesner's work, "Die Rohstoffe des Pflanzenreiches," is in course of publication by the firm of W. Engelmann, Leipzig; and the second and third parts have just appeared. The work will be completed in two volumes, and will probably be completed towards the end of this year.

A NEW edition of Thompson's "Gardener's Assistant," which has for many years been accepted as a trustworthy repository of information on the science and art of gardening in all its branches, is in course of publication by the Gresham Publishing Company. The work has been completely revised and entirely remodelled under the direction and general editorship of Mr. William Watson, of the Royal Gardens, Kew, and contains contributions by many eminent horticulturists. The first volume has just been published.

THE first volume of a "Cyclopedia of American Horticulture"—a work described as "comprising suggestions for cultivation of horticultural crops, and descriptions of the trade species of fruits, vegetables, flowers, and ornamental plants, together with geographical data and biographical sketches," has just been published by Messrs. Macmillan and Co., Ltd. It is edited by Prof. L. H. Bailey, whose fertility in the production of excellent botanical books is really astonishing, assisted by Mr. W. Miller. The present volume extends from A to D, and contains 509 pages and 743 illustrations. The work will be completed in four volumes.

A COMPLETE and convenient cabinet of glass-blowing apparatus and materials, arranged especially for students or others using Mr. T. Bolas's book on "Glass Blowing," has been put on the market by the Camera Construction Company. Exercises in the manipulation of glass cultivate delicacy of touch and perception, and are therefore excellent as manual training for young people. In scientific work, and more especially in physical and chemical sciences, the ability to work glass is a very valuable accomplishment, and a cabinet which provides a ready means of obtaining practice in this art is a desirable possession for laboratories as well as private students.

THE question as to whether strontium and barium can replace calcium in plants has been made the subject of inquiry by more than one experimenter. The February number of the *Bulletin* of the College of Agriculture of Tōkyō contains an interesting contribution to this question by Dr. U. Suzuki. Experiments were carried out with several species of plants and in soils containing varying amounts of calcium. The results show that strontium and barium can never replace calcium in phanerogams, as they are strongly poisonous, although the poisonous action may be lessened to a certain extent by the addition of lime salts. The *Bulletin* also contains papers by the same author on arginin, and its formation in coniferous plants; and by K. Asō, on the chemical composition of the spores of *Aspergillus Oryzae.*

AMONGST the products of the action of fluorine upon sulphur recently investigated by M. H. Moissan (see NATURE, April 19, vol. lxi. p. 597), thionyl fluoride, $SOF_2$, the existence of which was first indicated by M. Meslans, was noticed. MM. Moissan and Lebeau have now made this fluoride the subject of a more detailed study, and have succeeded in obtaining it in a pure state by two different methods—by the action of fluorine upon thionyl chloride, and by the interaction of fluoride of arsenic upon thionyl chloride. Thionyl chloride is a colourless gas, fuming slightly in moist air, and possessing an unpleasant odour resembling carbonyl chloride. It is easily condensed by a mixture of solid carbon dioxide and acetone, giving a liquid boiling at $-32°$. In the absence of moisture, glass is not attacked by the gas at temperatures below 400° C.; above this temperature silicon tetrafluoride and sulphur dioxide are produced. Water decomposes thionyl fluoride slowly at ordinary temperatures, giving hydrofluoric and sulphurous acid. Indications were obtained of another oxyfluoride of sulphur, not absorbed by water and possessing a much lower boiling point.

THE additions to the Zoological Society's Gardens during the past week include two Wild Swine (*Sus scrofa*, ♀ ♀), European, presented by the Lord Carnegie; three Chaplain Crows (*Corvus capellanus*) from Southern Persia, presented by Mr. B. T. Ffinch; a Herring Gull (*Larus argentatus*), European, presented by Mr. J. W. Berry; two Red Howlers (*Mycetes seniculus*, ♂ ♀) from Colombia, a Great Kangaroo (*Macropus giganteus*, ♂) from Australia, an American Flying Squirrel (*Sciuropterus volucella*), three American Box Tortoises (*Cistudo carolina*), a North American Trionyx (*Trionyx ferox*), three Changeable Tree Frogs (*Hyla versicolor*) from North America, a Black Sternothere (*Sternothoerus niger*) from West Africa, two Greek Tortoises (*Testudo graeco*), South European; six Argentine Tortoises (*Testudo argentina*) from the Argentine Republic, a Red and Yellow Macaw (*Ara chloroptera*) from South America, two Black-headed Caiques (*Caica melanocephala*) from Demerara, a Chough (*Pyrrhocorax graculus*), British, deposited; two Brown Mynahs (*Acridotheres fuscus*) from India, a Brown Mock Thrush (*Harporhynchus rufus*) from North America, an Occipital Blue Pie (*Urocissa occipitalis*) from the Western Himalayas, purchased; two Thars (*Capra jemlaicus*), five Swinhoe's Pheasants (*Euplocamus swinhoii*), bred in the Gardens.

## *OUR ASTRONOMICAL COLUMN.*

PHOTOGRAPHIC OBSERVATION OF EROS.—A circular from the Centralstelle at Kiel furnishes particulars of the photograph of the planet Eros obtained by Prof. Howe, of Denver Observatory, U.S.A., during the recent total eclipse. The position determined was:—

R.A. 23h. 47m. 3·9s. } 1900 May 27·9129.
Decl. + 2° 46′ 33″ } Greenwich Mean Time.

OCCULTATION OF SATURN.—There will be an occultation of Saturn by the moon on Wednesday evening, June 13, the particulars of which are as follows:—

| | Sidereal Time. | Mean Time. | Angle from | |
|---|---|---|---|---|
| | | | North Point. | Vertex. |
| | h. m. | h. m. | ° | ° |
| Disappearance ... | 15 7 ... | 9 40 ... | 89 ... | 116 |
| Appearance ... | 16 19 ... | 10 52 ... | 265 ... | 283 |

The planet rises about 8.55 p.m., so that the conditions for observation will not be very favourable.

HARVARD COLLEGE OBSERVATORY.—In *Circular* No. 50 issued from the Harvard College Observatory, Prof. E. C. Pickering reviews the methods adopted in the measurement of photographic light intensities. Since 1887 all the photographs obtained at the Observatory have had the image of a standard light impressed upon them for comparison. The methods now adopted have been developed by Mr. E. S. King, under whose direction the photographs are taken at Cambridge, and his description of the plan followed occupies the greater part of the circular. All sources of light, that of the sun, moon, sky, Milky Way, aurora and stars are to be referred to one standard, given by the meridian photometer, with which Polaris has a magnitude of 2·15. The artificial standard for practical convenience is that given by an Argand burner behind a small aperture; but this is compared with Polaris every month, when a series of tests are made on a 8 × 10 in. plate, the various parts of which are then cut and stored for future inspection. These monthly comparisons in addition furnish a valuable check on the constancy of the plate and the developer used, and will, moreover, as the several parts of the divided plate are developed at different periods, furnish data concerning any change in the image dependent on the interval between exposure and development. Spectroscopic photometry is also adopted to record the photographic intensity in terms of light of a particular wavelength.

Prof. W. H. Pickering has evolved a method of reducing the standard of comparison to the actual radiation received from a certain star shining directly on the plate. This unit, however, being so small, secondary and tertiary standards have been made from it by using lenses of known aperture and focal length. Thus, with a simple plano-convex lens of 8·2 cm. aperture, the image of α Ursæ Minoris was received on a piece of ground glass placed 3 cm. from the photographic plate. The "sensitive tint" was produced after twenty minutes' exposure, and the intensity of the light was calculated to be thirty times greater than the direct radiation from the star. For lights of great intensity this secondary standard is still too small, and then recourse is had to the Argand burner constant.

LIVERPOOL OBSERVATORY.—We have received the report of Mr. W. E. Plummer, the director of the Liverpool Observatory at Bidston, Birkenhead, on the work done in the year 1899. Although the seismograph has not been in use all the year, it is intended to commence keeping a continuous record of earth movements by means of the present instrument and one to be supplied by the Earthquake Committee of the British Association. The two will be placed so as to record movements in planes at right angles to each other.

The report contains detailed results of all meteorological observations during the year, including temperature, barometric pressure, rainfall, sunshine and cloud, wind velocity, humidity, &c.; and an appendix is added containing a summary of the mean values of many of these quantities during the past thirty years.

TEMPERATURE CONTROL OF SPECTROGRAPH.—In the *Astro-Physical Journal* (vol. xi. pp. 259–261, 1900), Prof. W. W. Campbell describes the arrangement he has finally adopted for securing as complete uniformity as possible of the temperature of the various parts of the spectrograph used at the Lick Observatory for determining stellar velocities in the line of sight. The whole instrument is first enclosed in two thicknesses of thick grey blanket, the prism case having an additional two thicknesses over it. Outside the whole is then fitted a case of cedar, lined with felt, in which is embedded a length of German silver wire. This latter is heated by an electric current, the strength of which is so regulated that a thermometer placed in the prism box shows as constant reading as possible. The efficiency of the device is clearly shown by a table giving the actual variations observed during a night's work. From 8.28 p.m. to 4 a.m. the temperature of the air in the dome varied from 17°·2 C. to 19°·0 C., but the extreme readings of the thermometer in the prism box were only 18°·70 C. and 18·84° C., so that the maximum variation was less than one-fifth of a degree.

## *ADVANCEMENT OF ELECTRICAL CHEMISTRY.*

IN a previous article (March 1, p. 428) upon the advancement of electrical chemistry, various developments of electrometallurgy or electrical deposition of metals were described. Electrolytic processes for obtaining the non-metallic elements and for the preparation of inorganic and organic compounds were left for consideration in a separate article, and are now dealt with.

In the year 1800, Nicholson and Carlisle showed that water could be decomposed into oxygen and hydrogen by means of a "volta pile"; since that time the electrolytic decomposition of water has been employed as a lecture experiment to show the composition of water. It is, however, only quite recently that oxygen and hydrogen have been produced on a manufacturing scale by the electrolysis of dilute solutions of caustic soda or sulphuric acid. The hydrogen so obtained is usually almost absolutely pure, but the oxygen is generally mixed with about 3 per cent. of hydrogen, which, however, can be removed by passing it through red-hot tubes.

The powerful oxidising action of ozone has through the advancement of electrical science been pressed into the service of the manufacturer. The methods employed for its production are all more or less based upon the well-known Siemen's tube. Generally speaking, air and not oxygen is ozonised, the air to be ozonised being freed from dust and from excess of moisture, the last of which causes formation of hydrogen peroxide. The temperature should be kept as low as possible, because at low temperatures oxides of nitrogen are less liable to be formed and the quantity of atmospheric oxygen converted into ozone is increased; indeed, some manufacturers cool the air down to 4° C. before subjecting it to the electric discharge. For convenience of use the ozone is generally compressed into iron cylinders under a pressure of from four to five atmospheres. It is used for refining and bleaching linseed and palm oils, and for the manufacture of oxidised oil for linoleum. Brewers are often troubled with fouling of the beer barrels; this seems to be due to the growth of a fungus which often penetrates the wood to a considerable depth, so that ordinary methods of cleansing fail to remove it. The oxidising action of ozone has been successfully employed to remove this growth, the method being to alternately steam and ozonise the casks. It has also been utilised to remove fusel oil from alcohol, in the purifying of water, the refining of sugar in place of animal charcoal, and in a great variety of other manufacturing processes.

It is well known that synthetical diamonds have been obtained by means of the electric furnace; charcoal obtained from sugar is rammed into a wrought iron cylinder, which is then closed with a plug. The cylinder so filled is placed in a bath of molten iron kept at a high temperature in an electric furnace, after which the crucible which contains the iron is rapidly cooled by immersion in melted lead. On dissolving the iron in acid minute diamonds are obtained. It was a question whether here we had a case of simple crystallisation of the carbon from the molten metal on cooling, or whether the enormous pressure which was exerted upon the interior of the mass by the rapid cooling of the outside acting upon the carbon at a high temperature caused the formation of crystals of diamond. An exceedingly ingenious experiment which has been carried out by Majorana shows that at any rate the influence of high pressure and high temperature combined is sufficient to convert amorphous carbon into the crystalline variety. Majorana's experiment is as follows:—

A cylindrical chamber, A (Fig. 1), is hermetically closed at the top by a solid block of iron, E, the bottom by a solid piston, S. The sides of the chamber are made of tempered steel, and to further strengthen it the chamber is surrounded by fifteen iron rings 1 cm. thick, which are bolted together. The whole system is placed within an hexagonal frame, K, also made from iron plates. The piston, S, has a small solid iron cylinder about 1 cm. in diameter attached to it, at the end of which is fastened a small piece of carbon, C, about 2 grms. in weight. Directly below the piston a thick block of iron, *p*, is fixed, into which a hole exactly the size of the small end of the cylinder has been drilled. In carrying out the experiment the carbon is heated by means of the two carbon poles, D, D′, with a current of 25 amperes and 100 volts. When the carbon has become white-hot, 70 grms. of gunpowder contained in the chamber A is exploded, the piston being driven down, carrying the heated carbon before it and compressing it with enormous force. On taking the system to pieces the carbon is found to have been partially converted into microscopic diamonds, which when freed from unchanged amorphous carbon are found to possess all the characteristics of natural diamonds.

Reference has already been made to the importance of the manufacture of calcium carbide; another carbide, that of silicon, is now being manufactured in considerable quantities, and, owing to its extreme hardness, is being employed in place of emery for polishing steel and making grindstones. This carbide, which goes under the name of "carborundum," is manufactured by means of the electric furnace. An American company at Niagara Falls employs furnaces capable of dealing with ten tons of material, consisting of coke, sand, common salt and sawdust, which yield two tons of carborundum in twenty-four hours. In the first half of the year 1897 it is stated that in America alone 750,000 lbs. of carborundum were manufactured. Since the introduction of electricity to chemistry the carbides of almost all the metals have been obtained, the majority naturally being more of theoretical than of commercial interest.

From the days of Leblanc, the founder of the soda industry, perhaps no branch of inorganic chemistry has been more worked at, or has better shown the results of patient toil and inventive genius, than the alkali and bleaching industry. Only after many attempts and many failures has the seemingly simple task of electrolysing sodium and potassium chloride yielded results which have enabled electricity to enter into competition with the former methods of manufacture.

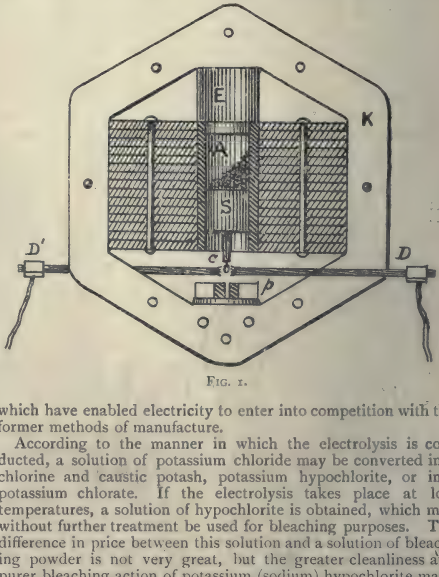

FIG. 1.

According to the manner in which the electrolysis is conducted, a solution of potassium chloride may be converted into chlorine and caustic potash, potassium hypochlorite, or into potassium chlorate. If the electrolysis takes place at low temperatures, a solution of hypochlorite is obtained, which may without further treatment be used for bleaching purposes. The difference in price between this solution and a solution of bleaching powder is not very great, but the greater cleanliness and purer bleaching action of potassium (sodium) hypochlorite make it, when electric power can be easily obtained, at least a powerful competitor with bleaching powder. When the electrolysis is conducted at temperatures from 60° and upwards, the bath being kept slightly alkaline by addition of potassium bicarbonate or lime, potassium chlorate is produced, which, owing to its slight solubility in water, crystallises out, and by washing readily freed from adhering chloride.

If caustic potash and chlorine are required, some arrangement must be made to prevent the liberated chlorine from again reacting with the caustic potash formed at the same time. Formerly, and still to a small extent, this was arranged by means of a diaphragm which separated the anode from the kathode. Owing, however, to the difficulty of obtaining a *pervious impervious* diaphragm, *i.e.* one which allows the current to pass, but is impervious to the solution, it is now more general to electrolyse without a diaphragm. The method employed is one which was originally employed by Castner and

Kellner, the kathode being a layer of mercury at the bottom of the bath. On the current being passed, the potassium liberated at the kathode dissolves in it, forming an amalgam, which as it is formed is drawn off and run into pure water, the water being decomposed, assisted by an auxiliary current, with evolution of hydrogen and formation of caustic potash, which is obtained in the pure condition by evaporation. Carbonate of potash may be prepared by passing a stream of carbonic acid gas into the caustic liquors before evaporation. In commerce, naturally, it is more general to electrolyse the cheaper sodium chloride, at any rate, in this country. Strontium and barium chlorate are also manufactured by electrolysis of their chlorides.

It has been found possible to prepare painters' colours by electrolysis, *e.g.* "white lead" is obtained in a very pure condition by electrolysing a dilute solution of sodium chlorate and carbonate, the electrodes being of lead. If the sodium carbonate is replaced by sodium chromate, a neutral lead chromate is produced, an acid chromate being formed by cautious addition of a solution of chromic acid during the electrolysis.

To attempt to mention, much less to describe, the enormous number of inorganic compounds and elements which have been prepared or isolated by the aid of electricity, would be, in an article such as this, impossible; but sufficient examples have been given to show the importance of electrical processes in this branch of chemistry.

Turning now to organic chemistry, we notice that, although a vast amount of work has been done, it is more of theoretical interest than of technical value. But now that the initial difficulties have been to a large extent overcome, and the manner in which the reactions take place is better understood, it is probable that shortly this branch of manufacturing chemistry will also undergo a revolution in the hand of the electro-chemist. As a means of synthesis and of proving the formula of substances, electrolysis has been, and is, of great value to the organic chemist. Thus on electrolysing a solution of an alkaline acetate, ethane is produced; whereas by employment of a succinate, ethylene is formed, a solution of fumaric acid yielding acetylene. These are, of course, simple cases; but even that seemingly unsolvable problem, the constitution of camphoric acid, has been attacked by Walker, and by means of electrolysis of it and its derivatives he has obtained results which must be of great value in ultimately deciding what is the correct formula for this substance.

Iodoform can now be produced in a state of great purity by electrolysing a solution of potassium iodide and sodium carbonate to which alcohol has been added. On electrolysis, employing electrodes of platinum, iodine is continually set free at the anode, and coming in contact with the alcohol at the moment of its liberation produces iodoform. As the reaction proceeds some of the iodine becomes converted into hydriodic acid, and this combines with the alkali liberated at the kathode, or which has been added to the bath, potassium iodide being regenerated, which by the further passage of the current is again split up. The process is a continuous one, the iodoform being from time to time removed and a further quantity of alcohol, potassium iodide and sodium carbonate added. It is interesting to note that the alcohol cannot be replaced by acetone, as in this case only a very small quantity of iodoform is produced. Chloroform and bromoform have not been successfully prepared by this method. Chloral can, however, be produced by electrolysis of a solution of potassium chloride at 100°, to which alcohol is from time to time added.

By the electrolysis of nitrobenzene in a strongly acid alcoholic solution, aniline is produced. If the nitrobenzene is suspended in concentrated hydrochloric acid, ortho- and para-chloraniline are formed. By electrolysis under other conditions, azobenzene, hydrazobenzene or azoxybenzene are obtained.

By the electrolytic oxidation of aniline, dye products can be obtained the nature of which depends upon the solution employed, the strength of the current and the material of the electrode, *e.g.* if an aqueous solution of aniline hydrochloride, which may be either acidified with sulphuric acid or be practically neutral, is electrolysed, platinum electrodes being employed, a green precipitate is produced at the anode, which becomes violet, bluish-violet and finally almost black, practically the theoretical quantity of aniline black having been formed. If the aniline contain toluidine, then mauveaniline, rosaniline, &c., are produced.

Attempts have been made to obtain alizarine by electrolysis of anthraquinone in strong alkaline solution; indeed, small quantities are said to have been obtained.

It has even been found possible to utilise electricity in the dyeing of cloth. When, *e.g.* a piece of cloth is soaked in a solution of aniline sulphate and placed between two metal plates, which are connected with opposite ends of a dynamo, and the current passed, the aniline sulphate is converted into aniline black; indeed, by altering the strength of the solution and the density of the current, shades varying from green to deepest black can be produced.

In the case of indigo the cloth is thoroughly impregnated with a thin paste of indigo-blue and caustic alkali; it is then placed between two metal electrodes. On the current being passed, the insoluble indigo-blue is converted by reduction into the soluble indigo-white, which on exposing the cloth to the action of air becomes again oxidised and the material dyed blue. Patterns may be printed on the cloth by cutting or stamping the plates in relief, or by connecting one pole to a metal plate and the other to a metallic pencil, when patterns, &c., can be readily sketched upon the material (Goppelsroeder).

Such processes as have been described in these articles appear, when seen in print, as extremely simple. Theoretically they may be so; but in practice, the carrying out of these seemingly simple operations is often attended by great difficulties. For example, the temperature must not be allowed to rise too high or fall too low. The quantity of current and its potential require often to be kept within extremely narrow limits, as the following simple example illustrates.

Silver and copper can be separated by means of electrolysis, the silver alone being deposited if a very low current density (·10 ampere) is employed, whereas with a higher density (·50–1·0 ampere) the copper is deposited. Naturally, then, if at the commencement of the operation the higher current density is employed, both metals will be deposited together. Many of the difficulties to be overcome are to a large extent engineering. And it is to a considerable extent due to collaboration of chemists and engineers that the science of electro-chemistry has become what it is.

Electro-chemistry is quite in its childhood, but it is making marvellous and rapid progress. Works dealing with technical chemistry but a few years old require to be revised, owing to the alterations which this branch of chemical industry has brought about.

It is humiliating to realise that in this country there is hardly a book on the subject to be obtained, and in most cases even these are only translations from Continental works. And it is to be feared that unless this branch of chemistry becomes more studied than it has been up to the present, we shall find in the near future that electro-chemistry, both theoretical and practical, is the property of America and the Continent.

F. MOLLWO PERKIN.

---

## *ROAD LOCOMOTION.*[1]

THE author commenced by saying that the subject of mechanical propulsion upon common roads had now reached a point when it deserves the very careful consideration of mechanical engineers.

For many years the uses and importance of the traction engine have become more and more recognised, but its work covers only a portion of the field for mechanical propulsion on roads, and he went on to consider what has led to a general revival of a movement for lighter road-locomotives which about seventy years ago, in the days of Hancock and Gurney, reached a point that for a time appeared to be leading to permanent results of the most important kind, but which ended in complete failure. In one sense this revival is undoubtedly due to the passing of the Locomotives on Highways Act in 1896, previous to which, for more than twenty years, a law had existed which made it impossible for any self-propelled vehicle to proceed at a rate of more than four miles an hour. The immediate cause of the passing of this Act was the attention aroused in this country by the successful introduction of the motor vehicle for purposes of pleasure in France. The real causes of the present movement were probably to be traced to the gradual feeling amongst all classes of the community that modes of transport, both for purposes of pleasure and business, on the roads had not kept pace, or indeed had made little progress at all, compared with the great changes which had been effected in speed, comfort and convenience, in the direction of locomotion by rail.

---

[1] Abstract of a paper read before the Institution of Mechanical Engineers by Prof. Hele-Shaw, F.R.S., April 26.

The author went on to consider at some length the question of the conveyance of goods, and by means of a graphical diagram showed that up to forty miles motor vehicles, owing to the terminal charges, might compete with railways. The hygienic question and growing difficulties of traffic in large cities was next touched upon. Next the difficulties of the problem were considered, and it was shown that these difficulties were very great; and so far from the success of the railway system being an argument in favour of the immediate development of locomotion by road, the conditions of the problem were such as to involve improvement exactly in the opposite direction to that in which the railway locomotive has been successfully developed.

No doubt the progress of invention would enable a greater amount of power from a given weight of motor to be obtained; but the surface to be moved over, which is the real difficulty of the road locomotive, would remain the chief factor of the problem.

The first section of the paper was therefore devoted to the mechanical problem of the behaviour of the wheel upon the road, and the progress which has been made in this direction.

Under this head the whole question of resistance upon the road was treated, and the author made a strong point of the fact that there was very little data available for determining resistance upon roads at the high speeds now permissible, and with different kinds of tyres now in use. He gave diagrams of horse-power curves of resistance adapted to English measures from the "Tableaux Numerique et Graphique" of MM. Boramé and Julien, and a series of graphical results taken with the Viagraph of Mr. Brown, showing the nature of the shocks to a vehicle by roads of macadam, stone, asphalte and wood.

The subject of pneumatic tyres was then discussed, and also the question of wheels suitable for heavy traffic, and illustrations of a number of improved types of wheels for this purpose, which had been invented during the last year or so, were given. With any existing system in which four wheels are used, it was shown that the problem of road locomotion was difficult because of the concentration of the load upon such a limited area of support. Even for heavy traffic the pneumatic tyre might come into use in the future as it extends the area of resistence by yielding, so that the surface in contact is much greater than in the case of an iron-rimmed wheel, especially when running over stone sets or hard ground.

Beyond this, it is quite conceivable that, just as in railways the number of wheels has been largely increased until a modern bogie carriage has commonly twelve wheels supporting it, it may be found economical to support a motor vehicle also upon a much greater number than at present.

The steering of motor vehicles, which was the subject of the next section of the paper, is evidently a very important part in their design, and it may at once be said that with one or two exceptions the great majority of motor vehicles are steered upon the principle which was invented by Ackermann as long ago as 1818. The essential principle of the Ackermann system consists in replacing the pivoted fore carriage of an ordinary vehicle which has one axle for the two wheels, by two short pivoted axles each carrying one of the steering wheels. The conditions of correct running of the wheels are that when their plane is turned, their normals intersect on a point on the line of the axles of the driving wheels. The paper then went on to describe the various modifications of the Ackermann system.

The next section of the paper was devoted to a consideration of motive power and its transmission to the wheels, and under this head the particular uses and advantages of oil, steam and electricity were considered; although these various agencies have at the present moment fairly well recognised spheres of operation this must be by no means regarded as the final condition of things, or as giving a limitation to the employment of each of these types of motive power. Thus, although at present oil-engines are used for light motor vehicles and steam for heavy traffic, there are very ingenious steam motor-cars both in this country and abroad, while light oil-engines have been applied in France and also in this country in connection with heavy traffic.

Oil-engines, or internal-combustion engines, have by a process of the survival of the fittest been found so far best suited for light motors and pleasure vehicles. The cycle of the gas-engine is really complex, but these motors have been brought to a high state of perfection, so that upon being started they are found to work for long distances without any attention. If really well designed and constructed, and used with a moderate amount of care, they need little repairs or adjustment, while the objection of smell, vibration, and danger from the use of light petroleum spirit with a low flash point, have all been much reduced, while each year sees an increasing number of places in town and country where petroleum spirit can be obtained. Still the objections above-mentioned must be admitted to exist, and this, together with the great expense of pleasure vehicles, has to a certain extent hitherto prevented their introduction becoming general. Again, an oil-engine, which has little elasticity in regard to an increased demand for power when ascending a hill, requires elaborate gearing for change of speed, which may be after a time, if not at first when the car is new, a very noisy and objectionable feature. Heavy-oil engines for internal combustion have been tried for motor vehicles, but the difficulties of starting and smell have not yet been satisfactorily overcome.

Steam, or external-combustion motors, require not only a generator or boiler, but also a condenser, in addition to the steam-engine itself. The latter is not used with all motors, but in winter the cloud of steam which must be visible in damp cold weather at a little distance from the exhaust, even if the steam is superheated, really contravenes the Act, which states, "No smoke or visible vapour must be emitted, except from any temporary or accidental cause." Steam introduces a more complicated array of pipes and fittings, and requires more attention and skill in working, but it is highly probable that such improvements will be made in connection with steam motors, that no skilled attendant will be necessary. There is already at least one steam system which is entirely automatic, whilst others are to a great extent so. It is not too early to speak as to the practical and commercial success of any of the systems using steam, but if a condensing steam-engine, automatic in action, with a boiler which is perfectly safe from any fear of explosion, can be produced, it may safely be predicted that there is a great future before it, both for light and heavy traffic, as it would have the advantages of great power and elasticity, freedom from smell, and if using heavy oil, or even coal or coke, would be free from the danger and trouble incidental on the employment of light oil, especially abroad. Moreover, the ease with which a steam motor can be started and stopped, and more particularly reversed, cannot be over-estimated.

Fuels, other than coal, coke or oil, have been the matter of careful consideration by motor-car designers. The most promising of these is acetylene, which, as derived from calcium carbide, enables a much greater quantity of energy to be obtained from a given weight of fuel; but although it only requires one-fourth of the weight of calcium carbide to produce a given amount of work as compared with coke, the expense at present makes its use commercially impossible.

Electrical motors are clean, extremely convenient and simple, free from all vibration and danger and altogether an ideal type of motor. The limitations in the use of electricity are, however, very serious, and are discussed later in the paper.

The details of internal combustion motors are discussed under the six headings upon which their success more or less depends, viz.: (1) carburisation, (2) ignition, (3) starting, (4) governing, (5) balancing, and (6) cooling.

The subject of steam is then treated at considerable length, and types of the more important steam heavy motor vehicles, such as those of Thorneycroft, Simpson and Bodman, Musker, Coulthard, Bayley and Clarkson and Capel are given, together with various examples of water-tube and flash boilers, which may be said to be the two types of boilers specially suitable for motor vehicles on account of their high steaming capacity in proportion to their small weight.

In considering the actual results which have been obtained by motor vehicles, a distinction is made between pleasure vehicles and those for the conveyance of goods. For the former, the actual cost of working is not by any means the first consideration; in a large number of cases, in fact, the cost is comparatively of small importance. Questions of comfort, durability and safety, as well as freedom from liability to break down, are the chief points to be considered. These matters can scarcely be summed up except as the result of lengthy experience, and now undoubtedly that experience is gradually being acquired.

When we come to the question of goods traffic, the matter is of course entirely one of cost, including not merely the outlay, working and upkeep, but deterioration, which in road vehicles is exceptionally heavy. Extended trials of actual working are necessary for any final opinion of the relative merits of different types of heavy motor vehicles, and the author has fortunately been able to secure much valuable testimony of this sort on the subject.

A great deal, however, can be ascertained by careful trials, such as those which have been undertaken on two occasions at Liverpool (1898 and 1899), since measurements and data can be obtained with a staff of observers for a limited period, which could scarcely be secured in continuous working. The results of these trials are given in tables and also statements by the Chief Mechanical Engineer of the Lancashire and Yorkshire Railway, on the working of a Thornycroft motor wagon; the Engineer-in-Chief, Mersey Docks and Harbour Board; and the City Engineer of Liverpool, on the working of Leyland motor wagons; and by Mr. Bryan Donkin, on the tests of motor carriages at Richmond and Birmingham.

Looking at the whole question, it may be safely said that the motor vehicle has come to stay, and that its uses, both in peace and war, will rapidly and enormously develop. The public interest which is now seen partly by the immense number of patents taken out in connection with the industry, partly by the great growth of literature on the subject, and by the formation of automotor clubs, is not a mere transient thing, and although the motor vehicle is at present still somewhat of a *rara avis* upon our roads, it may not be going too far to think that the coming century will see a development of locomotion upon roads comparable with the development of locomotion of the railway in the century which, according to our individual views of chronology, is either past or so very nearly past.

## *THE UNIVERSITY OF BIRMINGHAM.*

THE present position of the scheme for the establishment of a Midland University was explained by Mr. Chamberlain, Chancellor of the new University, at the first meeting of the Court of Governors, held on Thursday last. In the course of his remarks, Mr. Chamberlain is reported by the *Times* to have said that it was desired to create a great teaching University, in which all who came to them for it should find efficient and complete instruction in every branch of knowledge. Again, they desired that their University should be a school of research. They were firmly convinced that that was necessary if it was to maintain its dignity and great position. They believed that those were the best teachers who were themselves constantly learning, and that without adding continuously to the common stock of knowledge they would not be fulfilling their duties. In order to secure those objects they ventured to ask for a further endowment of a quarter of a million sterling. To-day they were able to announce that they had already received promises of 330,000*l.*, the amount having been largely increased by the munificent donations of Mr. Carnegie, of an anonymous benefactor, of Mr. Charles Solcroft, and of Mr. George Kenrick.

They intended that their University should be a distinctive University. In what he had hitherto indicated there was nothing original, nothing in which they were likely to specially differentiate themselves from the other great Universities, especially from the modern Universities in this country and the older Universities of Scotland; but they hoped that their University would take some colour from its environment, that not only would it be a school of general culture, but that it would also practically assist the prosperity and welfare of the district in which it was situated by the exceptional attention which it would give to the teaching of science in connection with its application to local industries and manufactures; and this portion of their task had turned out to be much greater, much more responsible, than they anticipated. They were encouraged in undertaking it by the gift of Mr. Carnegie, which was specially to be devoted to the creation of a college of science, following somewhat the example which had been set by the great colleges in the United States of America; and Mr. Carnegie followed this up by a proposal that a deputation from the intended University should visit the chief seats of learning across the water.

Those who had read the report of the committee that had visited Canada and the United States would begin to understand how it was that we were behindhand in the preparation for that great struggle which must come, that commercial competition between nations in which the weakest would inevitably go to the wall. For what did they find established both in the United States and in our own colony of Canada? They found great institutions connected with a general University, with colleges of science occupying large spaces, in which the area was counted by many acres, fully equipped with proper buildings, with the most modern and complete machinery, with the latest scientific appliances, with laboratories for every conceivable scientific purpose; and in those great colleges a training was given such as they desired to see imitated in this country—a training based, as all education ought to be, upon a foundation of general culture, but specialised in its course, highly specialised according to particular and separate work which each student intended to undertake in life. As a result of this they began to see how it was that in America the great commercial and industrial undertakings, the manufacturers and inventors, found no difficulty whatever in obtaining the services of as many young men as they might require to manage and complete and develop their undertakings, all of them ready when they left college, not merely to deal with the ordinary routine and management of a business, but to bring to it the latest discoveries and to apply the highest science to its development. That was what they wanted in Birmingham, and they would not have the University which they all had in their minds until they had accomplished it.

All that was wanted was money. The committee had pointed out that to carry out this scheme with any completeness a further sum, partly for endowment, partly for buildings and machinery and appliances, of 155,000*l.* was required. He was quite convinced, even from an incomplete examination of the project, that they had under-estimated the cost. He thought himself that another quarter of a million was the smallest sum which they would require in order to put this portion of their undertaking upon a thoroughly satisfactory basis. Well, they must get it, and he anticipated that they would obtain it. He anticipated that they would obtain it from two sources. Nothing he thought was more striking to any one who had studied educational progress in America and in our great colonies than the readiness, the eagerness, with which men who had acquired great wealth had been willing to devote a considerable portion of it in sums to which we here, he was sorry to say, were almost unaccustomed, to the promotion of the higher education. It was the case in Canada, in the great Universities of Montreal and Toronto; it was the case in America, in Cornell, in the Stamford University, in the Chicago University, in the Columbia University; and it was also visible in the great donations which had been made to the older Universities of Harvard and of Yale. He could not doubt that the feeling that no better application than this could be found for wealth would grow among them about Birmingham, and that although they lived in a district which had hitherto not been remarkable for exceptional fortunes, yet which did contain many men of great wealth. They also would find a tendency, from which the University would derive advantage in the future, to make their contributions towards such purposes as he had described. He hoped that this might be the case, and he thought he might say that he had confidence that it would be the case, and they might expect before long that their funds would be largely increased from some such source.

## *UNIVERSITY AND EDUCATIONAL INTELLIGENCE.*

CAMBRIDGE.—Mr. Chawner, Master of Emmanuel College, has been re-elected Vice-Chancellor.

Mr. Frederick Harrison will deliver the Rede Lecture in the Senate House on June 12, at noon. The honorary degrees referred to last week will be conferred on the same day, at 3 p.m.

The Knightbridge Professorship is vacant by the resignation of Dr. Sidgwick, who has been seriously ill.

Mr. L. R. Wilberforce, of Trinity College, has been elected a University Lecturer in Experimental Physics in the place of Mr. W. N. Shaw.

A grant of 50*l.* from the Balfour Fund has been made to Mr. J. S. Budgett in aid of his researches on the development of Polypterus.

Dr. Allbutt and Dr. Collingridge have been appointed delegates to represent the University at the International Congress of Hygiene and Demography to be held at Paris next August.

THE 500th anniversary of the foundation of the University of Cracow will be celebrated to-day, June 7. Representatives will be present from most of the European universities.

MR. W. T. A. EMTAGE, principal of the Wandsworth Technical Institute, has been appointed Director of Public Instruction in Mauritius. The post has been newly created, and Mr. Emtage will have the oversight of all the educational work under Government in the Colony. His first task will be the organisation of a system of technical education.

AT University College, London, Andrews Entrance Scholarships of 30*l.* each have been awarded to Mr. L. Graham, of Mason College, Birmingham, and to Mr. C. E. K. Mees, of St. Dunstan's College, Catford. The Atchison Scholarship of 55*l.* per annum for two years has been awarded to Mr. R. E. Lloyd for the greatest proficiency as a student of the medical faculty and the hospital during the past two years. The Bruce medal has also been awarded to Mr. R. E. Lloyd for proficiency in pathology and surgery.

THE Senate of the University of London has resolved that one sum of 100*l.* be offered as the Rogers Prize open for competition to all the members of the medical profession in Great Britain and Ireland, for an essay upon the production of immunity in specific infective diseases generally; and with particular reference to any one disease on which the writer of the essay has made original investigations. The essay is to be sent to the Registrar, University of London, South Kensington, S.W., on or before June 1, 1901.

THE Yorkshire College, Leeds, is now one of the university centres that grant a degree to students of agriculture. At a meeting of the Court of Victoria University (on May 3) a report of the Council recommending the inclusion of agriculture as a subject for the B.Sc. degree was adopted. Among other requirements, the scheme provides that students before taking their degree must conduct at an experimental farm controlled by a College of the University an experiment on some agricultural subject, and submit a report of the same. Only those students who, before entering the University, have attended an agricultural school for two years will be exempted from this rule.

AN illustrated prospectus of the courses of chemistry and chemical engineering at the Massachusetts Institute of Technology has recently been received. The prospectus includes descriptions of the various chemical laboratories, and the accompanying illustration of the main laboratory of industrial chemistry is of interest as indicating the provision made, in one of the foremost technical institutions in the United States, for work by students taking a general course in chemical industries. The ordinary course in chemistry in the Institute extends over a period of four years, and embraces almost all branches of chemical science. The aim throughout the whole course of instruction is not only to impart the necessary professional knowledge, but also to teach the student self-reliance, to accustom him to habits of accurate thought and work, and to instruct him in the methods of investigation of new problems. The course is designed primarily to prepare students for actual work in connection with manufactures based on chemical principles, but it provides also for those who expect to become teachers of chemistry, and for those who intend to devote themselves to scientific research. The object of the instruction in industrial chemistry is to set before the students as fully as possible the present status of the chemical industries. The laboratory instruction includes the preparation of pure chemicals, and the refinement or purification of technical products, by industrial processes. Among the processes carried out in the laboratory are the manufacture of dyers' mordants, soaps, phosphates from bone ash, and soda crystals; and also the preparation of salts of ammonium, barium, calcium, iron, copper, tin, chromium, &c., from minerals or other crude material. In addition, about eighty lectures are given on the most important industrial processes, and excursions are frequently made to manufacturing establishments.

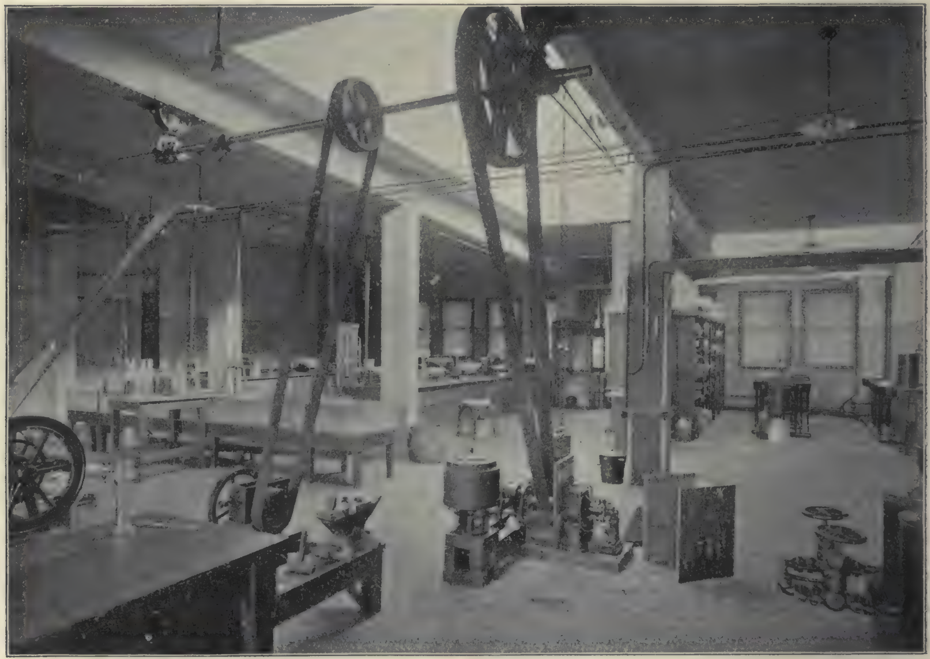

FIG. 1.—Laboratory of Industrial Chemistry of the Massachusetts Institute of Technology.

## SOCIETIES AND ACADEMIES.

### LONDON.

**Chemical Society**, May 17.—Prof. Thorpe, President, in the chair.—The following papers were read:—The chlorine derivatives of pyridine. VI. The constitution of some aminochloropyridines, by W. J. Sell and F. W. Dootson.—Ortho-substituted nitrogen chlorides and bromides, and the entrance of halogen into the ortho-position in the transformation of nitrogen chlorides, by F. D. Chattaway and K. J. P. Orton. When phenylacetyl nitrogen chloride undergoes transformation, a mixture of 95 to 96 per cent. of para- with 4 to 5 per cent. of ortho-chloroacetanilide is produced.—Ammonium imidosulphite, by E. Divers and M. Ogawa. A crystalline ammonium imidosulphite, $NH(SO_2NH_4)_2$ is obtained on allowing ammonium amidosulphite to decompose below 35° in a current of hydrogen or nitrogen.—The constitution of ethyl sodiocyanacetate and of ethyl methylsodiocyanacetate, by J. F. Thorpe. The reactions of ethyl sodiocyanacetate and of ethyl methylsodiocyanacetate are best represented by the formulæ $CN.CH:C(ONa)OEt$ and $CN.CMe:C(ONa)OEt$ respectively. —The $\alpha\alpha_1\beta\beta$-tetramethylglutaric acids, by J. F. Thorpe and W. J. Young. Ethyl sodiocyanacetate reacts with ethereal iodine solution, yielding ethyl iodocyanacetate, and under certain conditions gives an unstable diiodide which reacts with the excess of ethyl sodiocyanacetate giving ethylic dicyanosuccinate,  $\begin{array}{l}CH(CN).CO_2Et\\ |\\ CH(CN)\cdot CO_2Et\end{array}$. Ethyl methylsodiocyanacetate reacts with iodine, forming ethyl methyliodocyanacetate which condenses with ethyl dimethylacrylate, giving the salt $CO_2H.CH(CN).CMe_2.CHMe.CO_2Et$; the latter on distillation gives ethyl $\alpha$-methyl-$\beta\beta$-dimethyl-$\gamma$-cyanobutyrate,

$$CH_2(CN).CMe_2.CHMe.CO_2Et,$$

and this when hydrolysed yields $\alpha\beta\beta$-trimethylglutaric acid. The preparation of *cis*- and *trans*-$\alpha\beta\beta\alpha_1$-tetramethylglutaric acid is also described.—$\beta$-Isopropylglutaric acid and the *cis*- and *trans*-methylisopropylglutaric acids, by F. H. Howles, J. F. Thorpe and W. Udall.—Methyl iodide acts on the sodio-derivative of the product resulting from the condensation of ethyl sodiocyanacetate with ethyl $\beta$-isopropylacrylate, yielding ethyl $\alpha$-cyano-$\alpha$-methyl-$\beta$-isopropylglutarate. The latter on hydrolysis yields ultimately *trans*-$\alpha$-methyl-$\beta$-isopropylglutaric acid and its imide; the imide is converted into the *cis*-acid by heating with sulphuric acid.—The racemisation of optically active tin compounds. Dextromethylethylpropyl tin dextrobromocamphorsulphonate, by W. J. Pope and S. J. Peachey. Optically inactive methylethylpropyl tin iodide is wholly converted into dextromethylethylpropyl tin dextrobromocamphorsulphonate by treatment with the silver salt of the acid and evaporating the filtered solution; the new salt has the molecular rotatory power $[M]_D = +318°$ in dilute aqueous solution, but after heating and cooling the solution the value $[M]_D$ falls to $+273°$, which is the value $[M]_D$ of the acid in aqueous solution. After evaporating the solution to dryness and making up to the original volume by dissolving the residue in cold water, the value $[M]_D = +315°$ was obtained. It is thus proved that the asymmetric tin radicle

$$(CH_3)(C_2H_5)(C_3H_7)Sn-$$

can be easily racemised and easily converted into one optically active component.—Racemic and optically active forms of isoamarine, by H. L. Snape. The author has resolved optically inactive isoamarine into its optically active components by crystallising its tartrate; the dextro-base has the specific rotatory power $[\alpha]_D = +62{\cdot}02°$. The crystals of the optically active bases are orthorhombic and sphenoidally hemihedral.

**Linnean Society**, May 3.—Mr. C. B. Clarke, F.R.S., Vice-President, in the chair.—Mr. H. E. Smedley exhibited a number of botanical wax models prepared on an enlarged scale to show the morphological structure and also the process of reproduction in various types of plants.—Mr. J. E. Harting exhibited and made remarks on some skins of willow grouse collected by Prince Demidoff on the N.W. border of Mongolia between Alta Mountains and the Kobdo River.—On behalf of Miss E. S. Barton, the Botanical Secretary read a paper on a new species of *Halimeda* from Funafuti; and on behalf of Miss A. L. Smith, a paper on some West Indian fungi, with descriptions of a new genus and species.

May 24. Anniversary Meeting.—Dr. A. Günther, F.R.S., President, in the chair.—The following were elected into the Council:—Mr. Clement Reid, Dr. D. H. Scott, Rev. T. R. R. Stebbing, Prof. S. H. Vines, and Mr. A. Smith Woodward; and as President, Prof. Sydney Howard Vines, F.R.S.; Treasurer, Mr. Frank Crisp; Secretaries, Mr. B. Daydon Jackson and Prof. G. B. Howes, F.R.S.—The retiring President then delivered his annual address, choosing for his subject, "The unpublished correspondence of William Swainson with contemporary naturalists (1806–1840)," lately acquired by the Society.—The Gold Medal of the Society was then presented to Prof. Alfred Newton, F.R.S., in recognition of his important contributions to zoological science.

**Royal Microscopical Society**, May 16.—Mr. Carruthers, F.R.S., President, in the chair.—Mr. Chas. Baker exhibited two microscopes; one made specially for critical work was fitted with eye-pieces of the Society's new Standard gauge, No. 3, of 1·27 in. The other instrument, named the "Plantation" microscope, was designed for use in the tropics for the purpose of discovering the ova of internal parasites. Dr. Hebb said a paper had been received from Mr. Millett, being Part viii. of his report on the Foraminifera of the Malay Archipelago. This, as on former occasions, would be taken as read.—E. M. Nelson read a paper on the lag in microscopic vision, which he illustrated by diagrams and a series of tables showing the proportionate values of the performance of various objectives under eye-pieces of different powers. In the case of an apochromatic objective of fine quality, the degree of merit was shown to range from 14·7 with a low eye-piece, to 7·7 with a deep one, but the difference was more marked with ordinary dry achromatic lenses. Mr. Nelson's experiments had shown that in respect to the lag, microscopes with short tubes had some advantage over those with long tubes. Mr. Nelson also read a paper, for Mr. E. B. Stringer, on a new form of fine adjustment, a microscope by Messrs. Watson and Son, fitted with the arrangement, being exhibited. Mr. Nelson said that its working seemed exceedingly good. As the fine adjustment was placed just behind the body, the limb could be made of any length without putting additional strain upon the screw, a matter which would be of great advantage in microscopes made for examining large sections.—In announcing the adjournment of the meeting until Wednesday, June 20, the president said he hoped then to be able to submit and explain a series of lantern slides representing minute structure of some Palæozoic plants.

### PARIS.

**Academy of Sciences**, May 28.—M. Maurice Lévy in the chair.—Formation of nitric acid in combustions, by M. Berthelot. When sulphur is burnt in the calorimetric bomb in compressed oxygen under a pressure of twenty-five atmospheres, some nitrogen also being present, nitric acid is formed in quantities amounting to about ·001 of the sulphur present. At atmospheric pressure the amount of nitric acid formed is much reduced. With metals such as iron and zinc no nitric acid is formed.—Preparation, properties and analysis of thionyl fluoride, by MM. H. Moissan and P. Lebeau (see p. 137). —On the laws of specific heats of fluids, by M. E. H. Amagat. The formula $\frac{dC}{dp} = -AT\frac{d^2v}{dt^2}$ is applied to find the relation between the specific heat and pressure of carbon dioxide. The values of $\frac{dv}{dt}$ and $\frac{d^2v}{dt^2}$ were found graphically from the experimental data, and the results are given in the form of curves.—On some remarkable sub-groups of a group of substitutions or transformations of Lie, by M. Edmond Maillet. —On partial differential equations of the third order which admit of an intermediate integral, by M. A. Guldberg.—Formulæ giving the volumes of saturated vapour and the maximum pressure, by M. H. Moulin. The formulæ deduced from theoretical considerations by the author are compared with the experimental data of Young, Tate and Amagat for benzene, fluorbenzene, carbon tetrachloride, ether, acetic acid, methyl alcohol, water and carbon dioxide with satisfactory results.—The energy absorbed by condensers submitted to a sinusoidal difference of potential, by MM. H. Pellat and F. Beaulard.—The transparency of some liquids for electrostatc oscillations by M. A. de Heen.—On some photochemical effects produced by the wire radiating Hertzian waves, by M. Thomas Tommasina.—On a lithium peroxide, by M. de Forcrand. Since the combustion of lithium in oxygen gives only traces of a peroxide, attempts were made to prepare lithium peroxide in the wet way, by the action of hydrogen peroxide upon solutions of lithium salts. A thermochemical study of the products showed that some $Li_2O_2$ is formed in this way.—On the unknown earths contained in crude samaria, by M. Eug. Demarçay. The oxide isolated contains neither samarium nor gadolinium, and is of an atomic weight between these two elements. The chief lines of the spark and absorption spectrum are described.—The reduction of erythrulose and the preparation of a new erythrite, *d*-erythrite, by M. Gabriel Bertrand. Ordinary erythrite is easily oxidised by the sorbose bacterium to the ketone erythrulose,

$$CH_2(OH).CO.CH(OH).CH_2OH,$$

and this on treatment with sodium amalgam gives a mixture of two erythrites, one identical with the original inactive erythrite, the other, separated by means of its acetal, is active, possessing a rotatory power $[\alpha]^D = -4^\circ{\cdot}76$.—Action of cyanogen chloride upon acetone-dicarboxylic ethyl ester, by M. Juvénal Derôme. The cyano-derivative produced,

$$(CO_2C_2H_5).CH.CN.CH_2(CO_2C_2H_5),$$

readily forms metallic salts, the hydrogen adjacent to the cyanogen group being replaced.—On the metallic combinations of diphenylcarbazone, by M. P. Cazeneuve.—Osmotic pressure of the egg and experimental polyembryony, by M. E. Bataillon. —On the sub-fossil Lemuridæ of Madagascar, by M. Guillaume Grandidier.—On the discovery of a cave containing animal remains at Bains-Romains, near Algiers, by MM. E. Ficheur and A. Brives. The remains found include the bones of the species *Bubalus*, *Bos*, *Cervus*, *Antilope*, *Hippopotamus*, *Rhinoceros* and *Equus*. The presence of man was indicated by a molar, flint heads, and the presence of calcined bones.—Mode of action of antileucocytic serums upon the coagulation of the blood, by M. C. Delezenne. The mode of action appears to be identical with that of a peptone, the intravenous injection of a leucolytic agent being the same in all cases, the destruction of the white corpuscles circulating in the blood.—On the restoration to life obtained by the rhythmical compression of the heart, by MM. Tuffier and Hallion. A claim for priority against M. Batelli.

## DIARY OF SOCIETIES.

### *THURSDAY*, JUNE 7.

LINNEAN SOCIETY, at 8.—On a Viviparous Syllid Worm: E. S. Goodrich. —On the Genera Phæoneuron, Gilg., and Dicellandra, Hook f.: Dr. A. Itapf.—On the Structure and Affinities of *Echiurus unicinctus*: Miss Embleton.

CHEMICAL SOCIETY, at 8.—Diphenyl- and Dialphyl-ethylenediamines, their Nitro-derivatives, Nitrates, and Mercurochlorides: W. S. Mills. —Condensation of Ethyl Acetylenedicarboxylate with Bases and β-ketonic Esters: Dr. S. Ruhemann and H. E. Stapleton.—The Constitution of Pilocarpine: Dr. H. A. D. Jowett.—The Nitrogen Chlorides derivable from *m*-Chloroacetanilide and their Transformations: Dr. F. D. Chattaway, Dr. K. J. P. Orton, and W. H. Hurtley.—Derivatives of Cyanocamphor and Homocamphoronic Acid: Dr. A. Lapworth.

RÖNTGEN SOCIETY (St. Bartholomew's Hospital), at 8.—Dr. Lewis Jones will show an Influence Machine of American design.—Mr. James Wimshurst, F.R.S., will give a short statement of his work in the design and the perfecting of the several forms of his Influence Machine.—Dr. Rémy, of Paris, will show a new Localising Apparatus.

### *FRIDAY*, JUNE 8.

ROYAL INSTITUTION, at 9.—The Effect of Physical Agents on Bacterial Life: Dr. Allan Macfadyen.

PHYSICAL SOCIETY, at 5.—On the Magnetic Properties of Iron and Aluminium Alloys, Part II.: Dr. S. W. Richardson.—Note on Crystallisation produced in Solid Metal by Pressure: W. Campbell.—On the Viscosity of Mixtures of Liquids and of Solutions: Dr. C. H. Lees.

ROYAL ASTRONOMICAL SOCIETY, at 8.—Note on a Meteoric Shower South of Corvus: W. F. Denning.—Theory of the Motion of the Moon, Part III. Chapter vi.: Ernest W. Brown.—The Solar Eclipse of 1900 May 28 observed at Stonyhurst: Rev. W. Sidgreaves.—The Solar Eclipse of 1900 May 28 observed at Norwich: G. J. Newbegin.—The Total Solar Eclipse of 1900 May 28 observed at Navalmoral, Spain: Rev. S. J. Johnson.—*Probable Papers*: Description of the Durham Almucantar: R. A. Sampson.—The Cause of the Shadow Bands seen in connection with Total Eclipses of the Sun: G. Johnstone Stoney.

MALACOLOGICAL SOCIETY, at 8.—Note on Two Apparently Undescribed Species of *Bensonia*: W. T. Blanford.—The Non-marine Mollusca of Norfolk Island: E. R. Sykes.—Among the Exhibitions will be Specimens of *Volutilithes abyssicola*, *Eburna papillaris*, and *Bullia annulata* from South Africa, also *Cypraea nigricans*, together with other New Caledonian Cowries: G. B. Sowerby.—Dissections of the Genitalia of *Acavus*: W. B. Randles.

### *MONDAY*, JUNE 11.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—The Maintenance of Aëration as a Standard of Purity of Sewage Effluents: W. J. Dibbin and G. Thudichum.—The Composition and Determination of Cerium Oxalate: Dr. Frederick B. Power and Frank Shedden.—The Production of Nitrate of Soda in Chili: F. G. Welch.

### *TUESDAY*, JUNE 12.

ANTHROPOLOGICAL INSTITUTE, at 8.30.

ROYAL PHOTOGRAPHIC SOCIETY, at 8.—The Construction of Photographic Objectives: Mathematical Investigation: H. L. Aldis.

### *THURSDAY*, JUNE 14.

ROYAL SOCIETY, at 4.—Election of Fellows.—At 4.30.—*Probable Papers*: Some New Observations on the Static Diffusion of Gases and Liquids, and their Significance in certain Natural Processes occurring in Plants: H. T. Brown, F.R.S., and F. Escombe.—The Electrical Effects of Light upon Green Leaves (Preliminary Communication): Dr. A. D. Waller, F.R.S.—The Exact Histological Localisation of the Visual Area of the Human Cerebral Cortex: Dr. J. S. Bolton.—The Diffusion of Ions produced in Air by the Action of a Radio-active Substance, Ultra-violet Light and Point Discharges: J. S. Townsend.—Data for the Problem of Evolution in Man. V. On the Correlation between Duration of Life and the Number of Offspring: Miss M. Beeton, G. U. Yule, and Prof. K. Pearson, F.R.S.—On an Artificial Retina and a Theory of Vision, Part I.: Prof. J. C. Bose.

MATHEMATICAL SOCIETY, at 5.30.—Some Multiform Solutions of the Partial Differential Equations of Physical Mathematics and their Applications, Part ii.: H. S. Carslaw.—Some Quadrature Formulæ: W. F. Sheppard.—Notes on Concomitants of Binary Quantics: Prof. Elliott, F.R.S.—Extensions of the Riemann-Roch Theorem in Plane Geometry: Dr. Macaulay.—On the Invariants of a certain Differential Expression connected with the Theory of Geodesics: J. E. Campbell.—On the Constants which occur in the Differentiation of Theta Functions: Rev. M. M. U. Wilkinson.

## *MALAY MAGIC.*

*Malay Magic; being an Introduction to the Folklore and Popular Religion of the Malay Peninsula.* By W. W. Skeat. Pp. xiv + 685, and numerous plates and illustrations. (Macmillan and Co., Ltd., 1900.)

THE object of this interesting and important work is set forth on the title-page with such clearness that the reviewer and reader are spared some trouble in defining it, and it is pleasing to be able to say that the author exhibits the same clearness throughout the hundreds of pages which he has devoted to the discussion of his subject. Speaking broadly, Mr. Skeat's volume is divided into six sections or chapters, which indicate by their length the relative importance of the matters of which they treat, and the well-chosen illustrations do much to enlighten the reader of the work on many points which do not fall naturally under the heading of facts of folklore. Mr. Skeat's book differs greatly from the works on folklore which appear from time to time, for it contains, not only what seems to us to be an exhaustive statement of facts which he has collected and arranged with care and discretion, but a series of deductions made after due consideration of the general principles which have, consciously or unconsciously, guided man in all ages and in all countries in working out theories as to the relations which exist between the animate and inanimate in nature. Many travellers and sojourners in foreign lands and remote islands have written books on the folklore of their inhabitants, but the greater number of them have been characterised by haste, and by a lack of knowledge of the fundamental facts of primitive anthropology. Moreover, it has frequently happened that, although their writers have given their facts correctly, they have not given all that might have been given had their own knowledge of them at first hand been sufficiently good to draw forth from the natives all that might have been extracted from them. Mr. Skeat has given abundant time to his subject, and as he has relied for guidance in difficult matters upon such works as Prof. E. B. Tylor's "Primitive Culture," the non-expert will feel that he is in safe hands. Mr. Skeat's years of residence in the Malay States gave him unwonted facilities for collecting information, and his official position and knowledge of the native dialects enabled him to make the fullest use of his opportunities. Another fact must be remembered. The influence of the West upon the East grows stronger every year, and the systems of the white man and government according to modern Western ideas, which, sooner or later, he invariably succeeds in imposing upon the coloured man, are not favourable to the preservation of native superstitions and beliefs. Little by little they are set aside, and eventually they disappear; thus frequently it happens that information which the student of comparative folklore would consider priceless for his studies is lost for ever. Mr. Skeat has done well in collecting such information in the Malay Peninsula whilst it is still to be obtained, and we can only hope that other officials who have the time and opportunity for collecting anthropological facts may emulate his devotion and industry.

According to Malay views in general, the earth and the sea were formed, each in seven stages, after the light, which was an emanation from the Deity, had become the "world-ocean." The earth was surrounded by a ring of mountains which kept it in its place, and served as the abode for legions of spirits. This mountain is, of course, the old Arab mountain of Kâf, from which, as Yâḳûṭ says, "all other mountains are derived." Certain sages, however, hold other views, and describe how the Kábah, or home of the famous Black Stone at Mekka, the navel of the earth, was made immediately after God made himself manifest by his tokens the sun and moon. Next, the angel Gabriel killed the great serpent Sakátimuna, and the description of the subsequent disposal of her body forcibly recalls the Babylonian account of the fight between Merodach and Tiâmat. In fact, it seems pretty clear that Semitic cosmogonies have been drawn upon by the Malay theologians for several of the above theories. In shape, the earth is oval, and it revolves upon its own axis once every three months. Day and night are caused by the sun, which is a circular body moving round the earth. The sky is made of stone or "bed-rock," and the stars are merely holes which let light through from the place of light above. An earthquake is caused by the buffalo which supports the earth on its horns, throwing it from the tip of one horn on to the tip of the other; this buffalo stands on an island in the midst of the nether ocean. The tides are caused by a huge crab moving in and out of his cavern, which is situated at the root of the Pauh Janggi tree. Eclipses are the result of a monster dragon trying to swallow the sun and moon; and indeed any untoward movement in nature is attributed to the movements of beasts of enormous size or dragons.

The appearance of man upon the earth is accounted for in various ways, but it appears that all Malay explanations of his origin are based upon Arabic legends of the creation of man by Allah, who is said to have fashioned him out of earth, air, fire and water. The version of one legend, printed by Mr. Skeat on pp. 19–20, with its mention of Michael, Gabriel and Izrafel, proclaims the source from which it was derived. The body is composed of earth, air, fire and water, and with these elements are connected four essences—the soul or spirit with air, love with fire, concupiscence with earth, and wisdom with water. But the works of Arabic writers on such matters were not the only authorities consulted by the early Malay philosophers, for Greek authors of treatises on the composition of man are often quoted. Passing over the consideration of the sanctity of the body for want of space, we come to the mention of the soul, which is described as a thin, unsubstantial human image or mannikin, which is temporarily absent from the body in sleep, trance and disease; after the death of the body, the soul departs from it for ever. It is usually invisible, but it is supposed to be as big as the thumb, and to resemble the body in shape, proportion and complexion; it is of an impalpable, filmy, shadowy substance, and causes no displacement in the body into which it enters. It possesses all the attributes of the body to which it gives life, and it suffers from all its disabilities; sickness is supposed to be caused by its absence from the body, and the soul may be abducted from it by unlawful means. The human soul is seven-fold, and it seems, at times, as if each was independent, for in certain ceremonies an abode is provided for each. The idea that a man possesses several souls is very old, and in Egyptian religious texts it may be traced back to the period of the earliest dynasties, about six thousand years ago. The number seven is, of course, and always has been, a magical number, and in ceremonies which are intended to do good, as well as those in which the object is to do evil, it plays a prominent part. In Babylonian and Assyrian magical texts we find the seven evil spirits of the deep, and the Mesopotamian underworld possessed seven gates; it must not be forgotten, too, the famous temple of Nebo at Borsippa, which tradition identifies with the Tower of Babel, was built in seven stages.

When we come to discuss Malay gods, we find the subject to be one of some difficulty. In the old religion, which the Malay professed to throw off when he adopted Muhammadanism, his ideas had formulated the existence of a large number of nature powers which closely resemble the Hindu gods found in Brahmanism; and before he adopted these as the objects of his worship, he seems to have peopled heaven and earth with myriads of spirits. To this day, when in trouble, he cries out, not to the Allah preached by Muhammad, nor to the deities which the Brahman religion made known to him, but to the evil spirits which his ancestors worshipped and feared untold centuries ago. It has been the same in all ages and in all countries, and the nations which become "converted" to a new religion in reality only drop the observances connected with their old faiths; and although they may tear down the shrines of old gods and build others to new ones, they do not succeed in uprooting from their minds the beliefs and ideas of which the overthrown shrines were the outward and visible signs. In spite of the teaching of Muhammad and the Brahmans, the Malay still believes that every department of nature is presided over by a "god" who must be propitiated by man, and to be specially honoured and revered are such gods as Batara Guru, Batara Kala, Batara Indra, and Batara Bismu; the greatest of this group is the first. It is interesting to note that native influence has succeeded in introducing into the Malay pantheon a number of gods of the sea, which from certain aspects are identified with older terrestrial gods. Many of the Jinn, or evil spirits of the Arabs, have been identified with old Hindu spirits, and the view held by the Malay on the importance of such beings may be gathered from the fact that it was believed to be possible to buy them from the Shêkh of the Jinn at Mekka, at prices varying from ninety to a hundred dollars each!

More than three-quarters of Mr. Skeat's volume are occupied with a description of the magic rites which the Malay connects with the various departments of nature, and with the life of man. This is not to be wondered at, for it is clear at a glance that there is no event in his life, however trivial and apparently unimportant, which, unless properly protected by magic rites and ceremonies, may give hostile devils and fiends an opportunity for doing undreamed-of mischief to the wretched mortal whom accident or design has left unguarded. We regret that we cannot follow Mr. Skeat through his description of birth-spirits and birth-ceremonies, and through the whole period of a man's life from the cradle to the grave, as sketched by him, for our space is exhausted, and the reader can study for himself the curious Malay customs which concern betrothals, marriages and deaths. Many of them have their counterparts in other countries, but not a few are peculiar to the Malay. As we read of them we cannot help wondering how, if the pious Malay fulfils all his religious obligations, he ever finds time to do anything else. It is improbable in these days that many men are found who are able to carry out all the religious performances enumerated by Mr. Skeat, and it is much to be hoped that the influence of the English will drive many of them out of existence. Meanwhile a good and careful record of Malay sorcery, witchcraft and demonology, which is invaluable for the study of comparative religion and folklore, has been given us by Mr. Skeat, and there is no doubt that he has laid anthropologists and ethnographers and Oriental archæologists under a heavy debt of gratitude.

## *THE NANSEN NORTH POLAR EXPEDITION.*

*The Norwegian North Polar Expedition*, 1893–96: *Scientific Results.* Edited by Fridtjof Nansen. Vol. i. *The Jurassic Fauna of Cape Flora, Franz Josef Land.* By J. F. Pompeckj. With a geological sketch of Cape Flora and its neighbourhood by Fridtjof Nansen. Pp. 147; with 3 plates. *Fossil Plants from Franz Josef Land.* By A. G. Nathorst. Pp. 26; with 2 plates. *An Account of the Birds.* By R. Collett and F. Nansen. (London: Longmans, Green and Co., 1900.)

THE second chapter of the first volume of the "Scientific Results" of the Nansen North Polar Expedition opens with a geological sketch of Cape Flora and its neighbourhood by the leader of the expedition. It was a wise determination, on the part of those responsible for the publication of the results, to issue the several articles in English. The policy, too frequently followed, of writing important scientific papers in the language of the country where they are published, tends to place serious obstacles in the way of those who endeavour to follow the researches of Continental investigators. It is narrowness of view, rather than true patriotism, that compels authors to publish their results in languages which cannot be read by the great majority of scientific workers.

The geological investigation of Cape Flora, Franz Josef Land, was undertaken by Dr. Reginald Koettlitz, the geologist of the Jackson-Harmsworth Expedition, during the years 1894–97. Dr. Nansen's residence at "Elmwood," as the guest of Mr. Jackson, during a period of rather less than two months, afforded him an opportunity of visiting the most important localities in company with Dr. Koettlitz; the information he collected bears testimony to the good use which was made of this short visit. Nansen has given us a clear account, accompanied by diagrammatic sketches and photographs, of the geology of Cape Flora. This portion of Franz Josef

Land has the character of a plateau with a basaltic cap, 150 metres thick, composed of sheets of lava arranged in regular and almost horizontal terraces, which present a striking resemblance to the familiar basalt sheets in the cliffs of the Western Isles of Scotland.

From the face of the basalt a talus-slope extends to near the shore-line, where it passes into almost horizontal raised beaches, which occur at approximately the same level on both sides of the Cape, and point to a uniform and recent elevation. The volcanic rocks rest on Jurassic sedimentary strata, consisting for the most part of soft shale or clay containing numerous nodules of hard stone. From a "nunatak" protruding through the glacier, about 600 or 700 feet above sea-level, several fossil plants were found in fragments of shale spread over the surface of the rock within two small areas. The important question as to whether the shale was actually *in situ* and represented the remnant of an interbasaltic bed, or whether it had been broken off from a lower stratum and carried up by the intrusion of igneous material, has not been definitely settled. Nansen is of opinion that the plant-bed was *in situ*, and may be looked upon, therefore, as throwing important light on the age of the basaltic sheets; if this view is correct, the basalt must be assigned, on palæobotanical evidence, to an Upper Jurassic or Lower Cretaceous age. Very little is known as to the Jurassic deposits of Northbrook Island beyond Cape Flora; the beds examined at Cape Gertrude have yielded no fossils beyond fragments of wood and lignite. Nansen inclines to the view expressed by Messrs. Newton and Teall,[1] that the beds at Cape Gertrude were deposited under varying conditions and during oscillations of level; while the argillaceous sediments of Cape Flora, which are more uniform in composition, appear to have been laid down in a shallow sea during a period of comparative tranquillity.

The marine Jurassic fossils collected by Nansen from the rocks of Northbrook Island in the Franz Josef Archipelago are described by Dr. J. F. Pompeckj, whose work bears the stamp of thoroughness and accuracy. An account is given of previous literature relating to the Jurassic rocks of Franz Josef Land, special prominence being naturally given to the description by Mr. Newton of the fossils brought to England by the Jackson-Harmsworth Expedition. Some portions of the Cape Flora strata are fairly rich in fossils, but the fragmentary nature of the material renders accurate determination a matter of considerable difficulty, and in many cases the fragments are indeterminable. Dr. Pompeckj has performed his task with ability, and his conclusions have been arrived at as the result of careful sifting of the meagre evidence at his disposal. A glance at the comparative table of the Cape Flora fossils collected by the Jackson-Harmsworth Expedition and by Nansen shows that in several instances Pompeckj's determinations do not agree with those of Newton; considering the fragmentary nature of many of the specimens, it would be strange indeed if there were no discrepancies in the lists of the two palæontologists.

The fauna, as described by Pompeckj, is represented by the following genera:—*Pentacrinus*, *Serpula*, *Lingula*, *Discina*, *Pseudomonotis*, *Pecten*, *Lima*, *Leda*, *Macrodon*, *Amberleya*, *Macrocephalites*, *Cadoceros*, *Quenstedtoceras*, and *Belemnites*. The Ammonites appear to be abundant as compared with other groups, the genus *Cadoceros* being specially prominent as regards both species and the number of specimens.

Of the twenty-six species collected by Nansen, seventeen are new to the region, and five are considered to be new species. As the author points out, his results "differ in no slight degree from those which Newton arrived at from his examination of the Jackson-Harmsworth material." The sedimentary strata of Cape Flora are classed by Pompeckj as Lower Bajocian, Lower, Middle and Upper Callovian.

In the concluding palæo-geographical remarks, attention is drawn to the importance of the Cape Flora fossils as coming from the most northerly development of Jurassic rocks so far investigated. The occurrence of marine Bajocian species demonstrates "the existence of a Bajocian Sea in the north of the Eurasian-Jura continent." The extent of this northern sea cannot be determined, but the Jurassic sediments of Cape Flora afford evidence of deposition in shallow water near the shore-line of an Arctic continent. Neumayr's fascinating theory of climatic zones in the Jurassic period does not receive support from the palæontological results of Pompeckj and Newton; the scanty evidence at present available points to the existence of a decided central European facies in the fauna of Cape Flora, a fact opposed to the conclusions of Neumayr.

The patches of sedimentary rock from which Nansen obtained several fragmentary remains of plants have already been referred to as either portions of strata preserved *in situ*, or conceivably derived from lower strata and carried to a higher level by igneous forces. It is unfortunate that the history of the vegetation which flourished on the site of Franz Josef Land during the Mesozoic period is not represented by more legible records, but we may congratulate Prof. Nathorst on having exercised caution and care in the interpretation of the imperfect documents at his disposal.

Among the genera recognised by Nathorst are the following:—*Cladophlebis* and *Sphenopteris* fragments represent the ferns, small specimens referred to *Podozamites* and *Pterophyllum* may be accepted as evidence of the existence of Cycadean plants: *Ginkgo*, *Czekanowskia*, *Phoenicopsis*, *Feildenia*, *Taxites*, *Abietites*, *Pityanthus* and *Pityostrosbus* demonstrated the occurrence of Ginkgoales and Coniferæ.

The fairly numerous examples of small *Ginkgo* leaves are the most interesting fossils dealt with by Nathorst; they enable us to extend the range of the Mesozoic species of this isolated genus, which is to-day represented by the maiden-hair tree of China and Japan. The leaves named by Nathorst *Ginkgo polaris* bear a close resemblance to *Ginkgo digitata*, a species which played a prominent part in the Jurassic vegetation of several regions; the Franz Josef Land specimens are characterised by the small size of the leaves, and may possibly be regarded as a northern variety of the larger-leaved *Ginkgo digitata* of the Inferior Oolitic rocks of East Yorkshire. As regards the question of geological age, we agree with Nathorst's verdict that the plant-bearing beds must be assigned either to an Upper Jurassic or to a Lower Cretaceous horizon. Several of the plants suggest a comparison with Inferior Oolite species from the rich plant-beds of the Yorkshire coast, and it is not improbable that in the fragmentary fossils from Cape Flora we have the remains of a flora but slightly younger than that which has left abundant traces in the Lower Oolite strata of more southern latitudes. While admitting the danger of attempting to assign an exact geological date to the fragmentary and imperfect specimens, there can be no doubt that they must be referred to a period anterior to the Tertiary, and in all probability they are remnants of an Upper Jurassic flora.

---

[1] *Quart. Journ. Geol. Soc.* vol. liii. (1897), p. 477; *ibid.* vol. liv. (1898), p. 646.

While regretting that the fossils from Franz Josef Land are not more numerous and less fragmentary, we may offer a hearty welcome to the two able palæontological memoirs by Dr. Pompeckj and Prof. Nathorst; these authors, in carrying out their difficult tasks with thoroughness and good judgment, have set a standard of efficiency which promises well for the succeeding volumes of the "Scientific Results" of the Nansen Expedition. A. C. S.

As might have been expected, no birds new to science were obtained during the voyage of the *Fram*; nevertheless, some interesting observations were made on the range and distribution of bird-life in the high north, while naturalists have, apparently for the first time, been made fully acquainted with the early plumage of the roseate gull. In the course of the expedition birds were observed in the highest latitudes in which they are definitely known to be able to exist. During the summer of 1895, when the vessel was between 84° and 85° 5′ north lat., in the neighbourhood of Franz Josef Land, ten species were from time to time observed, although none occurred in any numbers. The one found farthest north was the Fulmar petrel, which was seen in lat. 85° 5′; in the last edition of "Yarrell" the extreme range of this bird is given as 82° 30′.

During the summer of 1896, when the *Fram* was north of Spitzbergen, the first herald of returning bird-life was a snow-bunting, which made its appearance on April 25. From the observations made during the same season, it is now evident that to the north of Spitzbergen, between lat. 81° and 83°, the Arctic Ocean is the resort of large numbers of birds, belonging, however, to comparatively few species. Apparently these consist for the most part of immature individuals, in the first plumage, which spend the summer among the open channels in the ice. The little auk and the ivory gull were among those most numerously represented; Sabine's gull having only been seen on a single occasion. Although swimming birds were by far the most numerous in these high latitudes, shore-haunting species were represented by the ringed plover and the grey phalarope, which were seen running about on the ice by the side of the open water.

The fasciculus is illustrated by an artistic plate of the roseate gull in its first plumage, which is mainly brown on the upper-parts, and therefore quite unlike that of the adult. R. L.

## THE CYANIDE PROCESS.

*The Cyanide Process of Gold Extraction.* By James Park. Pp. viii + 127. (London: Griffin and Co., Ltd., 1900.)

THE great success which has attended the introduction of potassium cyanide for the extraction of gold has created a widespread interest in this chemical process, and given rise to several books and papers on the subject from various authors. When we consider that at one large works 500 tons of gold are treated in twenty-four hours, we understand on what a colossal scale the cyanide method is worked. The process, like many others, has grown up from small beginnings, and it is largely owing to Messrs. MacArthur and Forrest that cyanide of potassium is now successfully applied to the treatment of gold ores in different parts of the world.

It is a most significant sign of the times that men who have been practically engaged in an enterprise are willing to communicate the results of their experience to the public at large, and from the manner in which the literature of the subject is growing, every detail requisite for economic working will soon be widely known and utilised. Therefore, one is not inclined to analyse the text too minutely, with the object of finding small flaws, provided the information is broadly reliable and accurate. It was inevitable that electricity should be brought into play in connection with such an important process, and we find Messrs. Siemens and Halske early in the field, with a method of depositing the gold on lead by means of electrolysis. There are two sides to this subject, as to most others, viz. the economic, or practical as it is termed, and the scientific. Now the former seems to be fairly well treated, but what is wanted is much greater attention to be paid to the latter, as it is possible that, with fuller and more intimate knowledge, potassium cyanide may be equally useful in the treatment of other metals besides gold, especially as it is now so largely used in the electro-deposition of gold, silver, copper, brass, &c. The work under notice has passed through three editions in New Zealand, and this is the first English edition. It is intended for the use of students, metallurgists and cyanide operators. Several new illustrations and tables are added, and the information relating to the treatment of slimes and the analysis of solutions has been greatly extended. It is gratifying to learn that wet crushing and cyanide treatment have been followed with as much success in New Zealand as in South Africa, although the ores are of a complex character.

The arrangement of the contents of the book is admirable. After a brief introduction and a general statement as to the limitations of the subject, the chemistry of the subject is wisely introduced, so that the student is at once brought face to face with the various reactions that occur, and led to see the reason for loss of cyanide, which is sometimes so excessive. Valuable information is given on pp. 10–13 on the action of potassium cyanide on metallic sulphides. A very useful chapter on laboratory experiments will be appreciated by teachers and students of metallurgy, as well as by the chemist and works manager; indeed, a commodious and well-equipped laboratory is one of the most important and necessary parts of a cyanide plant. The control, testing, and analysis of solutions is treated in a fuller manner than is usual with books of this class, and of the three methods given we prefer the silver nitrate test. The tables for the assay of cyanide solutions are a useful addition to this chapter. The appliances for cyanide extraction are briefly described, and although accompanied by several good scale drawings, certain details are omitted which might have been profitably included.

The synopsis of the process for the actual extraction by potassium cyanide is well written, and the conditions for successful treatment, such as strength of cyanide solution, &c., are stated as clearly as one could wish. Chapter vii. deals with the applications of the processes at different works. Leaching and precipitation are succinctly dealt with in Chapters viii. and ix. These are followed by a short description of the Siemens-Halske electrical process, which not only deposits the gold, but gives rise to the production of a number of valuable commercial bye-products, such as lead, copper, litharge and paint. For all those who wish to obtain a sound knowledge of the cyanide process, as conducted at the present time, we heartily commend Park's handbook.

---

## OUR BOOK SHELF.

*The Cause and Prevention of Decay in Teeth.* By J. Sim Wallace, M.D., B.Sc., L.D.S. Pp. 101. (London: J. and A. Churchill, 1900.)

THIS is a reproduction in book form of a series of articles published in the *Journal* of the British Dental Association.

The subject has been dealt with in the light of the now universally accepted chemico-parasitic theory of dental caries, but the author treats less of exciting or immediate causes than of those remote and predisposing. He attributes the great and increasing prevalence of dental caries among civilised nations to the elimination of the coarser and more fibrous parts of foodstuffs from the diet, and points out that this may act in two ways. Firstly, owing to the absence of mechanically detergent constituents of food, more of the fermentable, acid-producing and germ-sustaining parts of the latter remain in contact with the teeth for some time after meals. Secondly, that the tongue, being less actively employed during the act of chewing and swallowing, fails to attain its full size and exercise its normal important function in modelling the dental arches, so that irregularities arising from crowding and malposition of the teeth serve to intensify their predisposition to caries.

The subject is, on the whole, efficiently dealt with, and the book may be recommended to the medical practitioner or intelligent layman.

It is a pity, however, that the author lays such persistent stress upon what he considers the daring heterodoxy of his opinions, as these are at most modifications of those currently accepted. It is somewhat irritating, too, to find set forth for the instruction of the dentist, and with an air of great originality (as on p. 94), certain points in the operative treatment of caries which are among the very first impressed upon all students in schools of dental surgery.

Surely, too, the accusation of ignorance of the causes of the diseases he attempts to combat, and empiricism in practice, are undeserved by the educated dental surgeon of to-day.

HAROLD AUSTEN.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Atmospheric Electricity.

IN a letter on this subject in NATURE of March 29, Mr. Aitken criticises the theory which attributes the prevalence of positive electrification in the atmosphere to the superiority in efficiency as nuclei for the condensation of water vapour, of the negative ions over the positive.

That any difference in the degree of supersaturation necessary to make water condense on positively and on negatively charged ions would result under suitable conditions in the production of an electric field was pointed out by Prof. J. J. Thomson (*Phil. Mag.* vol. xlvi. p. 533), and it was suggested by him that this might be a source of atmospheric electricity. Experiments made by the present writer proved that there is such a difference, and that water vapour condenses much more readily on negative than on positive ions; while Elster and Geitel (and independently, Lenard) have recently brought forward evidence based on their own experiments and those of Liuss, tending to show the existence of free ions in the atmosphere.

There remains the question whether the necessary degree of supersaturation can ever occur in the atmosphere. Mr. Aitken contends that there is no such thing as dust-free air in the atmosphere, and that therefore any considerable degree of supersaturation is impossible.

Air practically dust-free does, however, seem to have been met with on Ben Nevis, accompanied by something very like supersaturation (Rankin, *Journ. Scot. Met. Soc.* vol. ix. p. 131). In Mr. Aitken's own papers, too, records of small numbers of dust particles (sometimes considerably less than 100 per c.c.) are not rare; and the lowest values are met with just under the conditions where their occurrence is of most significance. For "most of the low numbers in the tables were observed during rainy weather, and the very low ones in misty rain, when the clouds were at or near the surface of the earth" (Aitken, *Edin. Trans.* xxxvii. p. 664). Again, the purest air met with by Mr. Aitken was that blowing from off the Atlantic Ocean, the mean number of dust particles in a series of 258 observations extending over nearly five years amounting to 338 per c.c.; on one occasion the number was as low as 16 per c.c. (*Edin. Trans.* xxxvii. p. 666). Air coming from such a region can hardly be considered as abnormal. Moreover, such observations are necessarily made in air within a few feet of the ground; at a greater height it is likely to be less contaminated.

Consider a mass of air occupying 1 c.c. and saturated with water-vapour at 10° C., and let it expand till, say, $3\times10^{-6}$ gram. (less than one-third of the total water) has condensed to form 100 drops. Let us suppose the drops to be equal in size and let us calculate the volume and thence the radius of each drop, and from this obtain the rate at which they will fall relatively to the air (assuming the velocity $=\frac{2}{9}g\frac{r^2}{\mu}$, the viscosity $\mu$ being taken as $1\cdot8\times10^{-4}$). We obtain for the radius of each drop the value $1\cdot9\times10^{-3}$ centim., and for the rate of fall through the air, $v=4\cdot4$ cms. per second.

In a rising current of moisture-laden air containing 100 dust particles per c.c. there is thus no difficulty in seeing how the drops as they ascend may grow large enough to lag behind the air at the rate of 4·4 cms. per second (= 160 metres per hour); while the greater part of the moisture in the surrounding air is still retained as vapour. If then the upper surface of the cloud is carried to such a height that the drops reach the size $r=1\cdot9\times10^{-3}$ cm., it will there be lagging behind the rising air at the rate named, and a dust-free layer must exist immediately above it, increasing in vertical thickness at the rate of something like 180 metres per hour. Even if 1000 drops were formed in each c.c. of the cloud, the rate of growth of the dust-free layer would, as a similar calculation shows, when the same quantity of water had separated, amount to 34 metres per hour.

A difficulty raised by Mr. Aitken in connection with the removal of dust particles by condensation of water upon them is this: "When a cloud forms in ordinary impure air, only a small proportion of the dust particles become active centres of condensation, whilst many receive no charge of vapour." Instead of being an addition to our difficulties, does not this rather suggest a method by which, even if the air entering the base of a cloud be very impure, it may become freed from its dust? For it follows that even in such air a comparatively small number of drops will be formed in each c.c. when the saturation level is reached. What becomes of the nuclei which do not there form active centres of condensation? If the presence of a few slightly more efficient nuclei has prevented them from coming into play, the same number of actual drops will be at least equally effective in this respect. Will the dust particles then remain free until they are carried up beyond the reach of the drops, and there become active centres of condensation as Mr. Aitken suggests? It seems to me that, after a considerable vertical thickness of cloud has accumulated, this is highly improbable; such a cloud is likely to act as a very efficient air filter. For if even very impure air be kept in a small vessel with wetted walls the dust particles are removed in a comparatively short time—the shorter the smaller the vessel—by coming in contact with the walls. Dust particles in air travelling through a cloud must be very favourably situated for removal by contact with the drops. They are thus not likely to survive as free nuclei long enough to be able to come into play at the upper surface of the cloud, unless the time taken to traverse the cloud has been comparatively short. A cloud, due to an ascending air current containing near its lower surface as many dust particles (7700 per c.c.) as that encountered by Mr. Aitken on one occasion on the Rigi Kulm, even if it receive a continuous supply of equally or more impure air from below, may thus have no dust particles left in its upper portions beyond what are contained in the drops; while the number of drops per c.c. may amount to only a small fraction of the number of dust particles originally present, the size of each being correspondingly greater.

Mr. Aitken refers to the possible re-evaporation of drops due to the tendency of the larger ones to grow at the expense of the smaller. But all drops which have survived the great tendency to evaporate which accompanies the initial stages of their growth will surely continue to grow so long as the rate of expansion remains the same, or even if it be much reduced. The effect of the size of the drops on the vapour pressure necessary to cause water to condense on them is in fact relatively unimportant except in the case of very small drops; if we apply Lord Kelvin's formula to the case of drops even as small as $10^{-4}$ cm. in radius we find that the vapour pressure exceeds by only about one part in a thousand that over a flat surface of water; the evaporation from the drop of one part in 30,000 of its mass would cool it sufficiently to counterbalance this difference.

With respect to the power of sunshine to manufacture nuclei in air containing various gaseous impurities specified by Mr. Aitken, it may be observed that there is no evidence of such an effect of sunlight in normal atmospheric air, and that all the substances mentioned by Mr. Aitken (ammonia, nitric acid, &c.) being very soluble in water would be dissolved out of the air in passing through a cloud of water drops. It is true that sunshine does appear to produce in pure air nuclei (which however require a fourfold supersaturation to make water condense on them), and that strong ultra-violet light produces large nuclei like dust particles (*Phil. Trans.* 192, p. 403); but these effects have not, so far as I can see, any immediate bearing on the subject of the possibility of supersaturation in the atmosphere.

I do not know of any evidence to show whether the small drops in clouds tend to coalesce to form larger ones or not. Such coalescence would tend to hasten the process of separation of dust-free air from the cloud, by increasing the downward velocity of the drops relatively to the air; but it is unnecessary to assume its occurrence.

We have now seen reason for believing that the drops in the upper portion of a cloud produced in ascending air are likely, before the air around them has lost any very large proportion of its vapour, to have grown large enough to lag behind the ascending air at quite an appreciable rate; and that the air between them is likely to be dust-free. Under these conditions a dust-free layer will be formed above the cloud, and will continually increase in vertical thickness. This layer will be saturated with moisture at its lower edge, above this it will be supersaturated; the amount of supersaturation being greatest near its upper limit, and depending on the vertical distance through which the air has risen since escaping from the cloud. Now to produce in air initially saturated the supersaturation (approximately fourfold) necessary to cause water to condense on negative ions, it is sufficient to let the volume of the air increase adiabatically to 1·25 times its initial value (*Phil. Trans.* A, vol. cxciii. p. 289); an expansion which will result from an ascent of the air through a vertical distance of 2500 metres, if we suppose the air on escaping from the cloud to be at a temperature of 10° C. (at lower temperatures a smaller elevation would suffice). Thus, when the air in the uppermost layers of the supersaturated stratum has reached a height of about 2500 metres above the level at which it escaped from the cloud, a sudden change will result; condensation will there take place on the negative ions. The thickness of the supersaturated stratum (*i.e.* the vertical distance which the upper surface of the cloud has lagged behind the air), when the condensation on the negative ions begins, may vary greatly; it may be very small if the drops are small and the ascent of the air rapid; it may amount to nearly the whole 2500 metres in the case where the drops grow large enough to acquire a velocity relative to the air as great as the upward velocity of the air, so that the upper surface of the cloud has ceased to ascend. Above any cloud in an ascending air current, however numerous and small the drops, we should expect to find a supersaturated layer (possibly of very small vertical thickness), provided its upper surface has risen high enough for all dust particles to have either come into play as condensation nuclei, or to have been removed by coming in contact with drops already formed; provided also that the heating effect of sunshine on the drops at the upper surface of the cloud is not sufficient to counterbalance the cooling effect of the expansion and cause them to evaporate. And if the ascending current continues till a level about 2500 metres higher is reached, we get condensation taking place in the dust-free layer. It is difficult to avoid connecting this process with the sudden appearance of "false cirrus" at the top of a cumulo-nimbus cloud at the commencement of a shower.

We must now consider what will happen to the drops condensing from the supersaturated layer. Mr. Aitken takes the view that if condensation ever did take place on the ions, the drops formed would fall at once as rain, and that a cloud would never result. He remarks that the supersaturated air will be, as it were, in an "explosive" condition, which will cause the extremely rapid growth of any drop that may begin to form, thus preventing condensation on neighbouring ions. There is, however, no obvious reason for supposing the rate of increase of size of a drop in supersaturated air to be of a different order from that of the diminution in size of a similar drop in an unsaturated atmosphere. In neither case is there anything of the nature of an explosion. In the one case evaporation causes the lowering of the temperature of the drop below that of the surrounding air (to the wet-bulb temperature), the evaporation being thereby retarded; in the other case, the condensation on the drop at once raises its temperature above that of the surrounding supersaturated air, the rate of growth being mainly determined by the rate at which the drop can give out to the surrounding air the heat developed in it by the condensation. I do not think we have the data for determining whether the drops will fall at once as rain or remain in suspension till they have travelled into regions where the ascending current is insufficient to support them. In either case, if the drops fall through a supersaturated layer of some thickness, they are likely to reach the ground as negatively charged rain. I see, however, no reason to conclude that negatively charged clouds may not also be produced by condensation on the negative ions.

The foregoing considerations contain a theory of the origin of rain such as I had in view when the paper, criticised by Mr. Aitken, on the difference between the positive and negative ions as condensation nuclei was written (*Phil. Trans.* A, vol. cxciii. p. 289). That rain may sometimes at least have its origin in supersaturated portions of the atmosphere has indeed been held by v. Bezold, Cleveland Abbe, and other meteorologists.

I do not propose to consider what is likely to happen after the rain has begun to fall. It may be pointed out, however, that we are likely then to have a reduction in the supply of dust particles, especially if the rain extends over a considerable area; for the inflowing air is likely to have a considerable proportion of its dust particles carried down by the rain before it has penetrated any great distance into the rain-washed area. In Mr. Aitken's papers may be found references to the apparent dust-removing power of rain.

Mr. Aitken considers that the positive ions would not remain in the atmosphere, because a slightly greater supersaturation than was necessary to cause condensation in the negative ions would bring them down also. It is conceivable that they may sometimes be removed in this way; but if we consider that a greatly increased supersaturation (six-fold instead of four-fold) is necessary, and that the production of ions is continually going on, so that negative ions as well as positive are always present, we can hardly consider it a likely occurrence. What then is the subsequent history of the positive ions after being carried up out of reach of the drops formed on the negative ions? They will, under the action of the electric field produced by this separation, tend to travel downwards relatively to the air with a velocity of the order of one centimetre per second for a field of 100 volts per metre, as the measurements of Rutherford and others have shown. After being carried beyond the region of ascending air-currents, they will travel downwards towards the earth's surface; but long before reaching it they will become attached to cloud particles or to the dust particles of the lower layers of the atmosphere, where the positive charge will accumulate.

It is not claimed that the process described above is the only source of rain or the only source of atmospheric electricity. It should be pointed out, for example, that another way in which rain may possibly acquire a negative charge is by falling through ionised air. For according to Zeleny (*Phil. Mag.* vol. xlvi. p. 135) a body suspended in a current of ionised air becomes negatively charged in virtue of the slightly greater velocity of the negative than of the positive ion under a given force. Elster and Geitel make use of this difference between the positive and negative ions to account for the normal positive electrification of the atmosphere, by the passage of air through the vegetation on the earth's surface. Whether, however, the charged particles, the presence of which near the surface of the earth their experiments seem to prove, are really free ions whose velocity under a given force is that of the ions produced by Röntgen and other rays and not comparatively slow-moving masses (the nuclei called dust particles by Mr. Aitken) to which ions have attached themselves remains as yet undecided. In air charged with dust even to the extent to which clear air near the surface of the ground is shown by Mr. Aitken's observations to be, it is likely, since the rate of ionisation in the atmosphere is certainly slow, that an ion would become attached to some dust particle in a time very short compared with what the average life of an ion would be in dust-free air, where it is determined merely by the rate of recombination of the ions.

In conclusion, it must be confessed that if the rate at which the electric field of the earth is being destroyed by leakage through the air is anything like so great as is given by Elster and Geitel's interpretation of their experiments (*i.e.* of the order of 1 per cent. per minute), no theory which attributes the normal fine weather electricity to the effect of precipitation at a distance is sufficient to explain the facts. C. T. R. Wilson.

Cambridge Laboratory, Cambridge, May 16.

### Specimens of "Dromæus ater."

In reference to Prof. Giglioli's note (*suprà*, page 102), I may perhaps be allowed to remark that Bullock's Museum appears to have contained a specimen of the extinct *Dromaeus ater.* The twelfth edition of the "Companion" to that Museum, published in 1812, has the following entries (page 80):—

"Great Emea̬, or New Holland Cassowary . . .

"Lesser Emea̬, not half the size of the above, and a distinct species."

At the dispersal of his collection the sale Catalogue includes both specimens as lots 97 and 98 on the eleventh day of the sale (May 18, 1819), the latter as

"Lesser Emew̬, a distinct species from the last,"

and my annotated copy of the Catalogue shows that both were bought by the Linnean Society—for 10*l.* 10*s.* and 7*l.* 10*s.* respectively. I have tried to trace the latter specimen, but in vain. It may still exist unrecognised. Alfred Newton.

Magdalene College, Cambridge, June 4.

### Effect of Iron upon the Growth of Grass.

Some years ago Nature published a short letter of mine from India, noticing the way in which laying out iron (famine) tools on the ground brought on grass upon very dry surfaces. Any one who looks now under the rows of iron chairs, and round the railings, of the band-stand on the east side of the Green Park, will see the same stimulating effect produced. A. T. F.

London, June 4.

## SOURCES AND PROPERTIES OF BECQUEREL RAYS.

In the following article a general account is given of a few of the more striking phenomena connected with Becquerel rays, including some of the recent developments of the subject at the hands of Becquerel, M. and Mme. Curie and others.

Among a large number of papers which have lately been published, dealing with properties of these rays, two are worthy of especial notice, as giving a comprehensive view of the phenomena. For those who propose to study the subject more fully, no better guide can be found than Prof. Elster's report in Eder's *Jahrbuch für Photographie und Reproductionstechnik* for 1900. The footnote references to original papers form a complete bibliography of the literature of the subject existing at the time when the article appeared, and it is surprising that Prof. Elster should have succeeded in summarising so large an amount of matter in eleven very small pages. Dr. B. Walter's article in the *Fortschritte auf dem Gebiete der Röntgenstrahlen* is somewhat less condensed and more popular; the chief phenomena, especially the photographic and fluorescent properties, are dealt with at greater length, and the article is illustrated by a plate of radiographs showing the difference between the actions of Becquerel and Röntgen rays. Already Walter's paper, and, to a less degree, Elster's report, have become out of date on the subject of magnetic deviation, and for this and other later developments no better guide could be found than the well-condensed summaries contained in the current monthly parts of *Science Abstracts.*

The discovery of these rays in 1896 was a natural sequence of the discovery of the Röntgen rays, and was led up to, on the one hand, by the attempts of M. Henry to intensify the action of Röntgen rays by the use of phosphorescent substances; and, on the other hand, by the theory, since abandoned, that the Röntgen rays were themselves the result of phosphorescence of the vacuum tube. Becquerel and other physicists made numerous experiments to test whether phosphorescent substances emitted rays capable of acting on a photographic plate that was enveloped in opaque paper, and it was found that rays which produce actinic action were emitted by the phosphorescent salts of uranium, not only when these salts had been exposed to the action of sunlight or of Röntgen rays, but even after they had been kept in the dark for months, the "radio-activity" showing no perceptible falling off.

The next step was the discovery, by Mme. Curie, that Bohemian pitch-blende—a black, shiny ore of uranium—possessed a higher degree of radio-activity than uranium itself, and this result naturally suggested the view that the ore contained, besides uranium, some other substance to whose presence the increased action was due. By separating the pitch-blende into its constituents, M. and Mme. Curie were led to discover the existence of two sources of radio-activity, one associated with the compounds of bismuth, and the other with those of barium occurring in the ore. Seeing that barium and bismuth obtained from other sources do not emit Becquerel rays, these radiations were attributed to the existence of two new substances, that associated with bismuth being named polonium, a name derived from the Polish nationality of Mme. Curie, while the other substance associated with barium chloride was called radium. The separation of these two substances has led to the production of rays of sufficient intensity to excite fluorescent screens, discharge electrified conductors, and, indeed, to reproduce, with differences, most of the properties of Röntgen rays. A third radio-active substance, produced from the residues of pitch-blende, is recorded by Debierne, who names it actinium. It is precipitated by the principal agents for titanium, and it emits rays which reproduce the same phenomena as the rays emitted by radium and polonium, and are 100,000 times the intensity of ordinary uranium rays. Certain thorium compounds are also radio-active, a property first established in these by G. C. Schmidt and Mme. Curie, and subsequently investigated by R. B. Owens and Rutherford.

Since this article was in the printer's hands a paper by Sir W. Crookes on the radio-activity of uranium, read before the Royal Society on May 10, has been received. The author records an entire absence of radio-active effects in all the barium minerals in his cabinet from which uranium was absent, while pitch-blende and other minerals containing uranium and thorium excited a photographic plate. Arrangements were then made for working up half a ton of pitch-blende, and the radio-activity of the uranium salts was definitely traced to the presence of a foreign body, which Sir W. Crookes has christened for the time UrX (*i.e.* the unknown quantity in uranium), following a fashion initiated by Röntgen, and which has previously led to the introduction into our vocabulary of such terms as "Xd air" (Italian "aria Xata" or *ixata*). We would suggest the name "Crookesium" as a substitute. Whether uranium-X is or is not identical with radium seems not fully decided, but it appears to be distinct from polonium. It is now proposed to try to separate the radio-active component of thorium.

Le Bon, who claims to have anticipated the Becquerel rays in his "lumière noire," has expressed the opinion that the properties attributed to radium and polonium do not prove the existence of new elements, and may be accounted for by supposing the radio-active substances to be mere allotropic modifications of bismuth and barium. On this view there is no more fundamental difference between the properties of radio-active and ordinary barium than between phosphorescent and ordinary sulphuret of lime. Giesel, of Brunswick, also has adopted the terms "radio-active barium" and "radio-active bismuth" in preference to "radium" and "polonium." In support of the opposite view, Demarçay has proved that radium possesses a characteristic spectrum, and M. and Mme. Curie find that the atomic weight of radio-active barium chloride is greater than that of ordinary chloride, amounting in one specimen to as much as 146 as against 137.

The pitch-blende used in the preparation of these substances is obtained from Joachimsthal, in Bohemia. Under the direction of Giesel, working in co-operation with Profs. Elster and Geitel, the firm of E. de Haën, of List, near Hanover, have undertaken the preparation in small quantities of radio-active barium emitting rays that are unequalled in intensity, and have also placed on the market cheaper by-products which also emit rays of sufficient intensity to visibly excite a fluorescent screen. The solid radio-active compounds of barium increase in activity from the time of solidification, but do not reach their maximum for more than a month. The barium preparations are all luminescent, the chloride and bromide especially so when dry. According to Giesel, the bismuth or polonium preparations lose their radio-activity in a few weeks, and this property is also cited by Elster.

The radio-activity of barium bromide is found by Elster not to be destroyed by continuous heating for twenty-four hours *in vacuo*. After cooling, the strength is much reduced, but is restored after the lapse of a few days to nearly the original intensity.

Becquerel rays resemble Röntgen rays in their power of "ionising" air, a property they possess to such a degree as to discharge all conductors within a considerable distance of the radio-active substance. Their action on electric sparks has been studied by Elster and Geitel. A spark gap 1 cm. wide, consisting of a positive knob and a negative disc, was exposed to the radiations from a barium preparation. The sparks or brushes were converted into a violet glow-discharge, but the former discharge was re-established on interposing a plate of lead. With discs made of semi-conducting card the radium affected the discharge at the distance of over 1 metre. According to Elster, heating a small trace of a radio-active substance in air in a Bunsen flame increases the electric dispersion of the air of the room.

Becquerel finds many bodies acquire the temporary power of discharging conductors under the influence of the rays, thus affording proof that these rays involve a continuous emission of energy. The bodies do not, however, act on a photographic plate, and their activity is lost on heating. This property is not assumed by the double sulphate of uranium and potassium.

There appears at present no prospect of utilising Becquerel rays as a substitute for Röntgen rays in surgery. The difference of behaviour of the two kinds of rays is well shown by two radiographs of the human hand accompanying Dr. Walter's paper. In the one taken with Röntgen rays the outlines of the bones are remarkably clear and sharp; in the other, taken with the rays emitted by Giesel's most powerfully radio-active preparations, a dark, ill-defined shadow of the outline of the hand is seen, but not a trace of the bones is visible. This latter radiograph, which was taken with the relatively short exposure of an hour, shows clearly the shadows of a needle and of a coin that were placed under the middle of the hand, proving that a certain proportion of the rays had actually passed through the hand, but without differentiating the bones from the rest. Experiments undertaken by Walter to account for the hazy outline of the Becquerel radiographs point to the conclusion that the Becquerel rays, when passing through substances of small atomic weight, experience a far greater diffuse scattering than Röntgen rays. Further, the secondary radiations emitted by both light and heavy substances under the influence of the Becquerel rays differ far less from the incident rays in intensity and penetrability than in the case of the secondary rays investigated by Sagnac in connection with Röntgen rays. A further difference lies in the far greater absorption of Becquerel rays by specifically light substances, such as those forming the flesh of the human hand. With the use of a platinocyanide of barium screen, Walter observed the same absence of all traces of bones as with photographic methods, although the shadow of the hand was clearly seen on the screen.

The composite nature of Becquerel rays is suggested by experiments on phosphorescence and selective absorption, as well as on magnetic deviation. Mme. Curie has found that Becquerel rays are more easily absorbed when they have already penetrated an absorbing layer than when they have not. One aluminium disc absorbed a certain proportion of the rays; a second aluminium disc absorbed an even greater proportion of the remainder. According to the note on Mme. Curie's paper in *Science Abstracts*, "this is due to the fact that the less penetrative rays are absorbed in the first absorptive layers," but such a view would more naturally lead one to expect that the proportion of absorbed rays would be less at the second screen than the first, instead of greater; the phenomena can, however, be accounted for by the hypothesis that the first screen transforms the rays into secondary rays of lower penetrating power. The existence of such secondary rays has been supported by Villard, Meyer and Schweideler, Dorn and others. Becquerel has, however, shown that in the case of polonium rays from the Curies' preparations, no secondary rays are emitted by aluminium. The phenomenon of selective absorption has been studied by Becquerel, who exposed various substances to the action of radio-active barium chloride, including hexagonal blende, platinocyanide of barium, diamond, and double sulphate of uranium and potassium. The phosphorescence varied in different cases. When different screens were interposed—namely, aluminium, mica, black paper, glass, ebonite and copper—the absorptions of the radiations which excite phosphorescence in different substances by the same screen were found to be unequal. R. B. Owens has shown that thorium radiations resemble those associated with the derivatives of uranium ore, but possess greater variety. There are indications that they are not confined to so few distinct types, if, indeed, the number of types is limited. Becquerel shows that the absorption of "radium" rays by screens is variable according to the distance of the screens from the source, and that the intensity of the radiation decreases with the distance more rapidly than it would do according to the law of the inverse square; both of these are results of absorption by the air. The view advanced by Le Bon two years ago, that Becquerel rays could not be polarised, has been confirmed by Rutherford.

The magnetic deviation of Becquerel rays has absorbed a large amount of attention during the last few months, and conclusions from recent experiments have in several instances been in contradiction with the inferences from earlier investigations. Thus a survey of the literature of the subject shows that amongst others the following views have been advanced: (1) that Becquerel rays are not deviated; (2) that they are deviated in air but not *in vacuo;* (3) that the deflection gives rise to phenomena which are more marked with polonium than with radium; (4) that both radium and polonium rays are deviated *in vacuo;* (5) that radium rays show marked deviation, but polonium rays show no deviation whatever. The first negative result was obtained by Elster and Geitel; Giesel proved the magnetic deflection of the rays in air, and attributed the previously observed absence of deflections to the experiments having been performed *in vacuo.* Elster, by repeating the experiments with a different arrangement of apparatus, using the same radio-active bismuth and barium as in Giesel's experiments, has discovered the cause of his previous failure, and has established the magnetic deflection of the rays *in vacuo.* Giesel used a strongly radio-active bismuth preparation, and got more marked effects than with his barium compound; Elster, using a similar bismuth preparation and a relatively feeble one of barium, was led to infer that the barium radiations were the most deflected. In these experiments the rays are received on a photographic plate or fluorescent screen; P. Curie, on the other hand, has described an apparatus for comparing the magnetic deviation by means of the electro-dispersion produced by the rays. When not deviated the rays pass out normally between two lead blocks, and traverse the space between the plates of a condenser, causing a current to flow; when deflected the rays are absorbed by the lead blocks, and the current ceases.

Both Curie and Becquerel find that the magnetic deflection varies with different substances. According to Becquerel's paper of December 26, polonium showed no deflection, while radium showed a strong deflection. The absence of deflection in polonium rays has been observed by Mme. Curie, who states that they travel in a straight line. In comparing these results with the different conclusions obtained by Elster, reference must be made to Dorn's hypothesis, according to which it is suggested that the primary rays are not deflected, but are transformed into deviable secondary rays. But in a recent paper Becquerel finds that the Curies' polonium rays are neither deflected by a magnetic field of 10,000 C.G.S. units, nor are they transformed into deviable secondary rays. He has also made experiments to test whether the curvature of radium rays is affected by interposing a screen, as would occur if the transmitted rays were secondary rays moving with lower velocity. No such effect has been as yet observed. The most probable inference at present is that there are two kinds of rays, one deviable and the other not. The Curies find both forms coexist in radium rays; and from Giesel's experiments the deviable rays certainly exist in some preparations of polonium, but were doubtless not present to an appreciable extent in the samples experimented on by the Curies and Becquerel. According to Curie, the rays from radio-active barium carbonate are deflected to a very different extent. Those rays which have the greatest penetrative power are the most easily deflected, and those rays which are not deflected only penetrate air to a distance of 6 or 7 mm. Becquerel finds that magnetically deviable rays are absorbed by different screens up to a certain inferior limit of distance, while they penetrate a screen that is placed sufficiently near the source.

When the magnetic field is uniform and the direction of the rays is perpendicular to the lines of force, they describe circles and return to the starting point; when the rays start in a direction oblique to the lines of force, the paths are helices. These results have been recently verified by Becquerel, and from them it is possible to form a general prediction of the corresponding effects produced in a non-uniform field, such as that produced by a horseshoe magnet, which effects we now proceed to describe.

In Giesel's experiments, the sensitive plate was laid on the poles of the magnet, film downwards, the polonium being placed below and in contact with the film. Between the black patch produced above the substance and the dark zone produced by the deflected rays, a number of dark traces were observed, resembling wavy hair or like the ramifications in Lichtenberg's figures. Becquerel has shown that when the radio-active barium is placed on one pole of an electromagnet and a fluorescent screen on the other, the effect of exciting the magnet is to concentrate and contract the luminous area, a result unaltered by reversing the poles. When the rays pass across the lines of force, they, after proceeding upwards, are bent round and impinge on the plate along a curve, which extends from one pole to the other, bending out of the way of the radiant substance in the centre. When a piece of radium preparation is placed on a plate in a uniform field near a plane normal to the lines of force, the result is an intense impression limited by a spiral whose sense is that of the current which produces the field. This spiral is the trace, deformed by the field, of the line of intersection of the vertical plate and the plate on which the radium rests.

In the *Journal de Physique* for April, Becquerel shows that different radio-active compounds of barium emit rays that are equally deviated, and he establishes the fact that the deviation conforms to laws similar to those which apply to kathodic rays. The phenomenon of dispersion is established, and by interposing strips of paper, aluminium and platinum against the gelatine plate, on which the deflected rays are received, a kind of absorption spectrum is obtained, showing that the most deviable rays are the most readily absorbed under the conditions of the experiment. By calculating an inferior limit to $H\rho$ (the product of the magnetic force and the radius of curvature of the path) for the rays transmitted by various screens, the absorption by different substances is compared, and the results are of the same order of magnitude as for the kathodic rays. These and other facts suggest that part of the radiation is of similar nature to the kathodic rays, where small negatively-charged masses are transported with great velocity, and the Curies' experiments prove the existence of such charges, which, however, are exceedingly feeble. According to this view, the magnetic deviation is given by the formula $vm/e = H\rho$, and in an electrostatic field of intensity F the rays ought to undergo a deviation, $\theta = Fl \div (v^2 m/e)$, $l$ being the length of the path. It appeared, at first, that the electrostatic force required to make any such deviation visible would exceed the limit for which disruptive discharge would take place in air, and could only be obtained *in vacuo*. In a footnote, however, Becquerel tells us that he has since observed the electric deviation in air with a field of about $10^{12}$ C.G.S. units, and has found for certain rays which pass through black paper the values $m/e = 10^7$ and $v = 1{\cdot}6 \times 10^{10}$.

The chemical effects of Becquerel rays have been examined by M. and Mme. Curie and Becquerel; they may be briefly summarised here. The rays from active salts of barium transform oxygen into ozone, a process involving a continuous expenditure of energy. Potassium iodide is coloured blue. Glass in contact with the salts is coloured violet, ultimately becoming nearly black, and the colour penetrates the glass; this phenomenon is analogous to the coloration of fluorspar by kathodic rays. Platinocyanide of barium screens gradually turn yellow, then brown, and finally lose their fluorescence, which, however, is restored by exposure to sunlight. Fluorine continues to phosphoresce for twenty-four hours after being excited, and calcined fluorspar which has lost its phosphorescence regains its luminosity in the presence of radium. Chemical activity is confined to those radio-active preparations which are luminous, but is not always proportional to the luminosity.

According to the Curies' experiments, powerfully radio-active compounds of radium and polonium, when they act on inactive substances, are able to communicate radio-activity to them. This induced radio-activity increases with the time of exposure up to a certain limit. If the inducing substance is 5000 to 50,000 times the activity of uranium, the induced activity may amount to fifty times that of uranium. It is reduced to one-tenth of its amount in an hour after removal, but it may persist for many days, finally disappearing. The emanation of radio-active particles from thorium compounds, investigated by Rutherford, is remarkable. This emanation ionises the gas in its neighbourhood, and it will pass through thin layers of metal, through thicknesses of paper, or through a plug of cotton wool. It is also unaffected by bubbling through hot or cold water, weak or strong sulphuric acid. The emanation retains its radio-active power for some minutes, gradually losing it. The positive ion produced in the gas by the emanation was found to possess the power of inducing radio-activity in all substances on which it fell, this power of giving radiation lasting several days. Whether the emanation be a vapour of thorium is doubtful.

The question as to the amount of energy emitted by the Becquerel rays has already been referred to in NATURE, and need not therefore occupy our space further now. The problem of discovering the seat of this energy would seem of late to have taken another form. At first it was supposed that a difficulty would exist in reconciling the continuous emission of these rays with the principle of conservation of energy; now, however, that the amount of the emitted energy has been estimated, the difficulty is seen to lie in the experimental observation of changes of such inappreciable magnitude as would suffice to generate this energy.

Before 1896 physicists were just beginning to grasp Maxwell's theories, and to realise more clearly the simplification introduced into notions electric and optical by the conception of the ether. The discovery of rays capable of discharging electrified bodies in air has not only shown the fallacy of our preconceived dogmatic notions as to the division of substances into conductors and dielectrics, but has taught us that the properties of the ether are not so simple as we had anticipated. We can only wonder whether Maxwell would have been able to develop his electromagnetic and electro-optic theories had the complications arising from Becquerel and other rays been before him, and the want now makes itself felt of a second Maxwell, who shall co-ordinate the newly-accumulated mass of experimental facts into the form of a connected mathematical theory.

G. H. BRYAN.

## *MODERN MICROSCOPES.*[1]

IN spite of the attention which has of late years been paid to the improvements of every detail of microscope construction, it is remarkable how Powell's No. 1 stand has now existed, practically unchanged, for some fifty years. It may therefore be considered a permanent type, and it is one to which the best modern instruments conform more and more. Its most obvious peculiarity, however, a tripod base, has not yet become general. The heavy horseshoe foot is still in all but universal favour on the Continent, although Powell's base is occasionally imitated. Thus the Leitz firm in 1893, and the Hartnack firm in 1898, brought out large model microscopes on a tripod base; Greenough's low-power stereoscopic binocular microscope (1898) is similarly equipped. This last instrument, which is the most recent binocular novelty, is highly esteemed. It is made by Zeiss, is fitted with porro prisms, and, among other advantages, affords views of the *under* as well as the *upper* side of an object.

English makers have lately paid much attention to the perfecting of cheaper stands with some excellent results. In their new model and educational microscope, Messrs. Ross have reintroduced the principle of a reversing and locking foot, which was first invented by Cuff (*circa* 1765). By this means the instrument acquires great stability when used horizontally. The same firm, in their bacteriological microscope, use a tripod stand, of which the hind toe is made to fold forward between the two fixed front toes when not in use, thereby economising space in packing. The stage of this, as well as of Baker's microscopes, is fitted with the Nelson horseshoe perforation. The advantage of this device is that in high-power work, when the objective necessarily works very close to the cover glass, the slide can be tilted with the finger, and the focus gradually attained with far less risk to the object than if the slide rested immovably on the stage.

Messrs. R. and J. Beck's student's microscope and Messrs. W. Watson's "Fram" microscope are other examples of really good, small, cheap microscopes. Economy is obtained, not by sacrificing quality of work, but by simplifying the design. Every step in the direction of reducing the cost of a good instrument is too obviously desirable to require demonstration. Some designs strive after cheapness by using a fine adjustment, and trusting to a push-tube motion for the coarse. But if a microscope is to have only one adjustment, most microscopists will prefer a good coarse to an indifferent fine adjustment. This is the principle of Messrs. Watson's school microscope, which has a coarse adjustment only (diagonal rack and pinion), so good that a $\frac{1}{8}$-inch objective can be accurately focussed with ease. The cost, with eye-piece and objectives, is only three pounds.

The practical difficulty is, of course, that the great amount of wear upon the coarse adjustment affects in time the evenness of the racking, and produces loose action. But an important piece of progress towards obviating this trouble has been made by Mr. E. M. Nelson, who has applied the principle of stepped rackwork (Fig. 1). The two similar racks are placed so that their teeth are slightly out of step, the amount of divergence being regulated by the upper right-hand screw. The two screws in the centre of the pinion regulate the pressure by which the pinion is forced into the rack. The advantage of the arrangement is not only compensation for wear and tear, but rapidity and smoothness of action, for the tube obeys the slightest movement of the milled heads. If experience confirms the favourable opinion with which this novelty has been received, the necessity of a fine adjustment in cheaper stands will disappear.

---

[1] Fuller accounts of all the instruments referred to will be found in the *Journal* of the Royal Microscopical Society for 1897, 1898, 1899 and 1900.

Another coarse adjustment improvement has been made by Herr Reichert. Its principle is a rack and pinion of specially hardened gun-metal, and a very important feature is the springing with adjusting screws for tightening up. Of these there are three: one being used for regulating the grip on the tube-mount, the others for tightening the pinion; thus the unavoidable wear and tear can be compensated for.

Fine adjustments, owing to the rigorous requirements of high-power photomicrography, have received very great attention.[1] Modern advances may, however, be reduced to some five main types: (1) the direct-acting screw, (2) the same with lever interposed, (3) the differential screw, (4) Reichert's lever fine acting, (5) Berger's endless screw. The first of these is seen in the Zeiss' microscope (1886), where a left-handed micrometer screw with a hardened steel point presses on a hardened steel plate. In this, one revolution of the milled head causes a movement of 1/101 inch. The second is met with in Messrs. Watson's microscope, where a lever of the first kind with unequal arms is interposed. This arrangement not only greatly reduces the weight bearing on the fine adjustment, but slows the speed down to 1/350 inch for one revolution. This speed is not at all too slow, as any lens possessing a fair optical index is excessively sensitive to focal adjustment when a ¾ illuminating cone is used. The differential screw fine adjustment occurs in the microscopes of Messrs. Baker and Messrs. Swift. Its advantage is that fine movements are obtained by the use of coarsely threaded screws, thus reducing the liability to wear and tear. Any degree of slowness may be obtained, but 1/200 inch is adopted by the makers. Herr Reichert's fine adjustment is especially suited to the Continental model, and consists of an ingenious adaptation of a double lever of the second order to the usual direct-acting screw (Fig. 2). It is arranged for a movement of 1/200 inch.

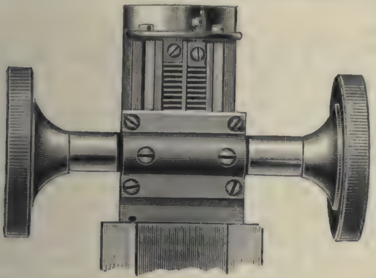

FIG. 1.

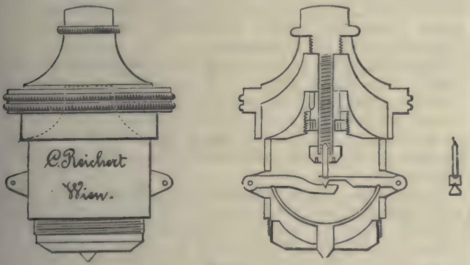

FIG. 2.

Herr Berger's (Zeiss) is another great improvement in fine adjustments, and is on an entirely novel plan. The extremity of the micrometer screw comprises a horizontal toothed-wheel, which is actuated by an endless screw, terminating in the usual micrometer knobs. This arrangement permits of any degree of sensitiveness, and is ingeniously packed away in a hollow part of the limb, so that the fine adjustment is both dust-proof and out of risk from any accidental injury. A valuable feature in the contrivance is a device for preventing strain on the fine adjustment from over-winding. This particular microscope is intended for the highest class of work, and possesses another good feature, in that the arm can be made to extend to any length over the stage without increasing the pressure on the fine adjustment. Thus an error in the original design of the Continental model, viz. the shortness of the distance between the limb and the optic axis, is corrected.

In Pillischer's international microscope a serious attempt has been made to reduce the inconveniences inseparable from stage-clips. He secures these to a bar, which, by means of a flange piece, raises or lowers them *simultaneously*, so that their points press on the object slide with any desired degree of pressure.

The use of large slides has led to a corresponding increase in the size of the stage, as well as in improved stage-finders and mechanical movements. There is a marked tendency to make the stages completely rotatory.

Among special stages, that of Herr Kraus (Reichert and Co.) is perhaps the most notable. It is heated by an electric current passed through a coil of platinum immersed in the liquid paraffin with which the stage box is filled. Regulation is accomplished by an ingenious contact thermometer, a device which resembles an ordinary thermometer, except that it is open at the top end. A platinum thread can be set in the tube at any desired temperature, and, when the mercury has risen and has met this thread, an automatic arrangement switches off the supply current. If the platinum and the mercury break contact, the current re-enters. The apparatus is said to be capable of rapidly producing and sustaining a temperature constant to 0·1° C.

In the department of lenses, Messrs. Watson have brought out their holoscopic eye-pieces, in which one lens-mount slides within the other, telescope fashion, thus forming a very convenient arrangement, easily adjustable as an over-corrected or under-corrected ocular as desired. The appropriate graduations are engraved on the tube.

Messrs. Zeiss have issued, at Dr. Hartwig's suggestion, a very useful series of low-power objectives, called "planktonsearchers," which are to be immersed in a trough of water, and so used for exploring it. They are made of Jena glass, and present an image completely plane and free from astigmatism quite close up to the periphery. The microplanar series of objectives by the same firm are used for projecting micro-slides on a screen, and give a wonderfully good ten-feet picture remarkably plane, sharp and well-defined, even to the limits of the field.

Another important set of objectives is Messrs. Leitz' series of achromatics. These are made of Jena glass free from fluorite. They are so well designed and corrected that they give results but very little inferior to the best apochromatics. Their freedom from fluorite renders the risk of atmospheric deterioration insignificant. Moreover, they are sold at so low a price that Messrs. Leitz must be admitted to have outstripped all other opticians in this particular detail.

Mr. H. J. Grayson, of Melbourne, has by an unknown process produced some very fine examples of ruled test-plates, the rulings being executed in various gradations of fineness, as far as 60,000 lines per inch, and 2000 lines per millimetre. The accuracy of the work is remarkable and the mounting in realgar ($\mu = 2\cdot5$) makes the lines stand out with a distinctness and brilliancy hitherto unknown.

---

[1] For fuller information see "On the Evolution of the Fine Adjustment," by Mr. E. M. Nelson (*Journal* R.M.S. 1899, pp. 366–375).

The Royal Microscopical Society have, after careful consideration and after full consultation with microscope makers, drawn up a code of standard sizes for eye-pieces and sub-stage fittings. It is to be hoped that this important and useful step towards universality will be generally adopted. ALFRED N. DISNEY.

## *THE FORTHCOMING MEETING OF THE BRITISH ASSOCIATION.*

THE meeting of the British Association, which is to be held in Bradford this year, promises to be an unusually large and important one. Bradford being midway between London and Edinburgh, serves as a common meeting-ground for scientific men from the south of England and from Scotland and Ireland, and it is within easy reach of the Midland and Northern University Colleges. Bradford and Leeds are so close together that for such a purpose as this they are almost one city, and the Bradford Committee, therefore, have the advantage of the Yorkshire College being practically on the spot. The last meeting of the British Association in Bradford was held in 1873, but since that time the city (which, by the way, was then only a town) has practically been re-built, and has grown and developed in a manner resembling the progress of an American rather than that of an English town.

It is, therefore, much better provided now with hotel accommodation and with public buildings suitable for reception and sectional rooms. It is probable that the number of visitors will be far above the average; already some sixty or seventy Fellows of the Royal Society have announced their intention of being present, and professors and eminent lecturers from nearly every University in England, Scotland and Ireland have promised to attend. The Church will be represented by the Bishop of Ripon, the legal profession by the Master of the Rolls and Lord McLaren, and the names of over a score of members of both Houses of Parliament have been sent in.

The meeting will commence on Wednesday, September 5, when the new President, Prof. Sir Wm. Turner, of Edinburgh, will deliver his address in St. George's Hall. On the following evening the Mayor of Bradford will give a conversazione in St. George's Hall, at which it is hoped there will be exhibits illustrating the most recent scientific work. On Friday evening the lecture will be delivered in St. George's Hall by Prof. Gotch, F.R.S., on "Animal Electricity." The lecture to artisans on the Saturday will be given by Prof. Silvanus Thompson, F.R.S., and it is expected that there will be an audience in St. George's Hall of 4000 to 5000 working men. On Monday afternoon the Mayor and Corporation will give a garden-party in Lister Park, and in the evening an address will be given by Prof. W. Stroud on "Range-Finders." The Mayor and Corporation will give another large conversazione on Tuesday evening, and on the Wednesday evening a concert will take place in St. George's Hall with the Permanent Orchestra and the Festival Choral Society, under the conductorship of Mr. Fredk. Cowan. There will also be one or two eminent vocalists.

During the week there will be a textile exhibition at the Technical College, which will illustrate the various processes of the local industries, and the machinery employed can be seen in motion. There will be a reception at the College on Thursday afternoon, September 6, and the smoking concert in honour of the President will also be given at the Technical College, after Prof. Gotch's lecture on Friday.

Excursions to places of interest in the neighbourhood will be made on Saturday, the 8th, and on Thursday, the 13th; among the places selected are Bolton Priory, Ripon and Fountains Abbey, Malham, Clapham and Ingleton, the Nidd Valley, Farnley Hall, Haworth, Ilkley, Knaresboro' and Harrogate.

It has become an established custom to publish locally in the towns visited by the British Association a handbook containing a review of the objects of scientific interest and of the social and industrial conditions which prevail in the district. Many of these handbooks have been excellent in their character, and have covered ground altogether unexplored by the ordinary guidebook.

There is every prospect that the handbook published in connection with the Bradford meeting of the Association will be marked by the same width of view and thoroughness of execution, and may prove of permanent value. The work has been taken up with energy by the Publications Committee, of which Mr. Harry Behrens is chairman, and Mr. Mortimer Wheeler is honorary secretary and editor.

The book will be divided mainly into three sections. The earlier will deal with the history of Bradford and the development of the Bradford trade, under the following sub-heads:—(1) Prehistoric archæology, for which Mr. Butler Wood, chief librarian of the Bradford Free Libraries, is responsible: (2) the historical record of Bradford through mediæval times to the middle of the 18th century, which has been undertaken by Mr. Harry Speight; and (3) the social life and development of Bradford from the middle of the 18th century to the present, which is in the hands of Mr. Halliwell Sutcliffe, the novelist. To this section there will be addenda on the local dialect, the local folklore, and the local place-names, including street-names, which will be written by Mrs. Wm. Wright (of Oxford) and Mr. Butler Wood.

The second section of the volume, of which Mr. John Bacchus is sectional editor, will deal comprehensively with the Bradford industries and institutions. The following are sub-heads:—Introductory notice and description of the staples employed in the Bradford trade; description of the processes in combing, spinning, weaving, dyeing and finishing; merchanting in the textile trade; the iron trade and machinery-making; the stone trade and minor industries; the Chamber of Commerce and the Exchange.

The third part of the book, which is under the sectional editorship of Mr. J. E. Wilson, will deal with the scientific material of the locality, the flora, fauna, geology, meteorology, climate and public health. There will be in addition a number of pages devoted to the topography of the district, for which Mr. J. H. Hastings is responsible.

In addition to the handbook, the Publications Committee have in preparation a series of small guides to the various places to which excursions are to be made. These will be issued in the form of a small portfolio, and each guide is being prepared on a scheme similar to that of the handbook, local specialists being called upon to describe the archæology, geology, botany and zoology of the various districts.

In regard to the accommodation of visitors, it is not anticipated that, in spite of the large influx of strangers, there will be any difficulty in finding comfortable quarters for everybody. Bradford is well provided with hotels, the two largest of which, the Midland and the Great Northern, can put up a great number of guests. All the available accommodation at the Royal Hotel has been secured by the local committee in order to provide for the secretaries of the different sections, who, of recent years, have been in the habit of lodging together. A large amount of private hospitality will be provided by the inhabitants of Bradford, and the Hospitality Committee is also drawing up a list of furnished apartments, which can be had on application. It is important, however, that all persons proposing to attend the meeting should give a long notice of their intention, in order to facilitate the arrangements which the Committee wish to make for their comfort. RAMSDEN BACCHUS.

---

## NOTES.

A Conference of delegates for the International Catalogue of Scientific Papers was held at the Royal Society on Tuesday and Wednesday.

The second of the two soirées held annually at the Royal Society will take place on Wednesday next, June 20. This is the soirée to which ladies as well as gentlemen are invited.

Mr. C. E. Borchgrevink will give an account of his Antarctic work at the meeting of the Royal Geographical Society on Monday, June 25, instead of June 18, as previously announced.

The annual visitation of the Royal Observatory, Greenwich, will take place on Tuesday, June 26. The visitation has previously been held on the first Saturday in June, and the change of the customary date is due to the absence of the Astronomer Royal, and other astronomers, for the purpose of observing the solar eclipse. This does not, however, explain the change of day.

On the occasion of the retirement of Sir Frederick Bramwell from the office of honorary secretary of the Royal Institution, the managers of the Institution unanimously resolved "to place on permanent record an expression of their high appreciation of the admirable way in which he has performed the duties of that office and of his signal services to the Institution generally."

The death is announced of Dr. Julius Althaus, the distinguished physician and neurologist. He was the author of works on "Diseases of the Nervous System," "Failure of Brain Power," "Diseases of the Spinal Cord," "Medical Electricity," "Influenza" and "The Spas of Europe," and was an authority upon the use of electricity in medical practice.

The next lecture of the Zoological Society of London will be delivered at the Society's Meeting Room, on Thursday, June 21, at 4.30 p.m., by Prof. E. Ray Lankester, F.R.S. The subject will be the gigantic sloths of Patagonia.

At the last meeting of the Royal Society of Edinburgh, the following were elected as British Honorary Fellows:—Dr. Edward Caird, Master of Balliol College, Oxford; Dr. David Ferrier, professor of neuro-pathology, King's College, London; Dr. G. F. Fitzgerald, professor of natural and experimental philosophy, Trinity College, Dublin; Dr. Andrew Russell Forsyth, Sadlerian professor of pure mathematics in the University of Cambridge; Dr. Archibald Liversidge, professor of chemistry in the University of Sydney; Dr. T. E. Thorpe, principal of the Government Laboratories, London; and, as Foreign Honorary Fellows:—Dr. Arthur Auwers, secretary, Royal Prussian Academy of Sciences; Prof. Wilhelm His, Leipzig; and Prof. Adolf Ritter von Baeyer, Munich.

The celebration of the centenary of the Royal College of Surgeons of England will commence on July 25 with a conversazione at the College. On Thursday, July 26, a centenary meeting will be held at the University of London, when an address will be delivered by the president, Sir William MacCormac, and honorary fellowships will be conferred. On Friday, July 27, there will be a conversazione at the Mansion House. The Committee have issued invitations to foreign and colonial surgeons, and propose to issue invitations to certain persons of distinction residing in Great Britain and Ireland. A short history of the College, with eight illustrations, has been prepared, and will be presented to guests invited to the centenary celebrations.

The new clinical laboratories of Westminster Hospital were opened by Lord Lister on Tuesday, in the presence of a distinguished company. The laboratories have been added to the hospital to provide for a more scientific and systematic examination of disease than can be carried out satisfactorily in the wards. A few particulars concerning the work of the hospital were given by Sir J. Wolfe-Barry, K.C.B., and are reported in the *Times*. Westminster Hospital was, he said, one of the oldest hospitals in London, having been founded in 1719. 30,000*l*. had been spent in bringing the hospital up to modern requirements, and in 1899 it was decided to add clinical laboratories and improve the isolation wards and nursing accommodation. In time they hoped to institute an electrical laboratory fitted with the apparatus for the Röntgen rays and micro-photography. To meet these expenses 10,000*l*. was wanted.—Dr. Lazarus-Barlow, in giving a detailed account of the laboratories, said the hospital tried to keep in front of all research and modern improvements, scientific and clinical. The laboratories contained all the most recent apparatus for the clinical work of the hospital.—Lord Lister said it was no less a pleasure than an honour to him to take part in that day's ceremony. The beautiful clinical laboratories they had inspected would give the physicians of the hospital an opportunity of bringing to bear on their cases the most advanced knowledge and the most refined methods of investigation. Many a diagnosis which would otherwise be obscure would be rendered clear in those rooms. He need hardly say that the correct diagnosis was directly proportioned to successful treatment. In respect of what Sir J. Wolfe-Barry had said, he himself felt convinced that those who had worked in the laboratories would not only benefit patients in the hospital, but would also, unfailingly, be able to extend the boundaries of knowledge and promote the now rapid advance of pathological and therapeutic knowledge. The laboratories would also be of service as a powerful means of affording sound practical knowledge to the student.

During the early part of the present week a wave of unusual heat has passed over parts of England, accompanied by brilliant sunshine. In the neighbourhood of London, the shade thermometer rose to 89 on Monday, the 11th inst., and thunderstorms occurred over several parts with heavy rainfall, amounting to an inch in the Midland Counties. So high a temperature has not occurred at so early a period of the summer in the neighbourhood of London for more than fifty years. A sharp thunderstorm also visited London about 10 a.m. on Tuesday, and another occurred in the evening; there was also a renewal of severe thunderstorms over a large part of England. The temperature on Wednesday was considerably lower than on the preceding days.

From St. Petersburg to Vladivostok by way of the Arctic Ocean is (says the *National Geographic Magazine*) the plan of itinerary of an exploring party that early in June leaves the former city on the steamer *Aurora*. Six men of science and twelve sailors, all experienced in Arctic travel and led by Baron Toll, make up the party. Their special object is the careful exploration of the Arctic regions north of Siberia. After a brief stop at Tromsö, Norway, and at the new Russian port of Catherine Harbour, on the Lapland coast, they will proceed to the Taimur Peninsula, west of the Yenisei River, and there establish their winter headquarters. The neighbouring territory is to be explored during the winter of 1900–1901. On the breaking up of the ice, about August 1901, it is proposed to push on to Sannikoff Land, discovered by Baron Toll in 1886 and as yet unexplored, and later farther northward to Bennett and De Long Islands, following the routes of the *Jeannette* in 1881 and of the *Fram*. The winter of 1901–1902 will be devoted to determining whether this group of islands extends to the Pole. When the water route reopens in 1902 they will resume their voyage to Bering Strait and reach Vladivostok in the autumn of the same year.

THE application of science to the great problem of mechanical traction is revealing the fact that at no distant date the motor car, or automobile, will be regarded a decided success in every respect. Electricity, steam and oil are still fighting for the paramount position of best agent for propulsion, and, on this account, trials and experiments always prove of interest. The *Engineer* (May 25) describes a series of trials for touring vehicles at the Paris Exhibition, and out of thirty-seven cars competing we find that three were driven by steam, and all the remainder propelled by petroleum motors. Among the more recent improvements on the heavier classes are smaller driving wheels; the motor still develops about six horse-power for cars carrying four or six passengers, their lower centre of gravity, owing to their smaller wheels, also proving an advantage when rounding corners at high speed. After exhaustive trials embracing distance, manipulation, grades, &c., medals were awarded to the makers of the following vehicles: the "Peugot" car, the "Delahaye" car, the "De Dietrich" car, and the "Panhard et Levasser" wagonette. All these are driven by petrol motors; for this kind of work, therefore, petrol stands in good stead, and it will be of interest to see whether this agent or steam is adopted for freight vehicles of a much heavier description.

THOUGH the articles upon scientific subjects in popular magazines can often only be called scientific by courtesy, yet we like to think that their presence in increasing numbers indicates a growth of public interest in the progress of science. *Pearson's Magazine* usually contains contributions which are instructive as well as interesting; and the reader who is no longer thrilled by episodes in the lives of freebooters, mysterious knights and similar personages over whom the glamour of the past may be thrown, must find relief by turning to the articles in which imagination is tempered with truth. In the June number of the magazine, we find an account of the destruction of the jack rabbit of the United States, by driving them into a corral, as described and illustrated in NATURE several years ago. M. Flammarion's experiments on the growth of plants under different coloured glasses, also described in these columns, form the subject of another interesting article. Mr. George Griffith concludes his story of imaginary visits to other worlds by means of a machine moved by a force with peculiar properties. If we may venture a criticism of this series of contributions, it is that Mr. Griffith's ideas are too anthropomorphic, and too limited by the present state of knowledge of the objects visited by his interplanetary travellers. Some of the work of the U.S. Fish Commission in pisciculture forms the subject of a short illustrated article; and an interview with Prof. Milne, illustrated by several seismograms, contains much interesting popular information upon earthquake waves. Finally, a number of reproductions of photographs of faces of athletes at the moment of victory are reproduced. The photographs are interesting to students of facial expressions, and a curious point revealed by them is that only in one case of the hundreds of photographs from which the selection was made is a pleasant expression upon the face of the winner.

A NOVEL way of making building land is being carried out not far from New York. The rapidly growing population of this city has made ground scarce on which to build villas and houses for the summer resort of the inhabitants; but the enterprise of the American builder is equal to the emergency, and land is now being literally pumped up from the sea, on which it is intended to erect houses, and to create a new suburb. The site chosen for this venture is the Nassau Beach, on the shore of Jamaica Bay, in Long Island, not far from Brooklyn. The salt marshes bordering on this coast, which for centuries have been overflowed by the tides, and which, of course, while in this condition were utterly unfit for building purposes, are being raised from four to six feet above high water by pumping up the sand, shells and gravel which form the floor of the bay, and delivering this on to the land to be reclaimed. The process adopted to attain this end is as follows:—A powerful suction dredger raises the material from the bed of the bay at the rate of 18,000 cubic yards a day, and with this five times the volume of water, which is sufficient to carry the sand and gravel along the twelve-inch pipes which deliver it on the low land. The water flows off by ditches along a more or less circuitous route back to the bay, the dredged material settling and quickly drying, and forming solid land. The thickness of the material when first deposited averages about eight feet, but there is shrinkage as it dries and consolidates. Ten acres have thus been raised since the pumping began a few months ago. A raised road and promenade two miles long and seventy feet wide, and an electric railway, will connect this new suburb with the railway to Brooklyn and New York.

WE have received the first numbers of the *Boletim Mensal* of the Rio de Janeiro Observatory. The work contains much useful information, chiefly contributed by Sr. L. Cruls, the able director of the Observatory, and it will form a welcome addition to current meteorological literature. As long ago as 1887, Sr. Cruls issued a large number of circulars to all meteorological organisations with the object of collecting data for a climatological dictionary. For want of adequate resources, this valuable compilation has not been published; but we are glad to see that he intends to utilise the bulletin for the publication of some of the principal results. The number for February contains the annual means and extremes for twenty-nine stations in Japan. Another paper worthy of special note is that by Sr. Pereira da Costa on the earliest observations made in Brazil.

READERS of Mr. Fitzpatrick's "Transvaal from Within" will recollect his reference in an appendix to a discussion which took place in President Krüger's Volksraad on the wickedness of firing guns in order to bring down rain. We learn from the *Corriere della Sera* that the practice of firing cannon as a preventive of hail has been adopted lately in Italy with successful results. On May 25, at about 17 o'clock or 5 p.m., three successive storms collected in the neighbourhood of Rogeno (Como), the clouds of which were evidently charged with hail. At a given signal fourteen cannon opened fire on the clouds, with the result that nothing fell except a little sleet, here and there. On the same day a vast amount of damage was done in the vicinity of Alessandria by hailstorms passing over the districts of Rocchetta, Tanaro, Masio, Felizzano and Quattordio about 16 o'clock (4 p.m), the hailstones in some places massing to a depth of 50 cm. In the districts where cannon were adopted for dispersing the hail, the results exceeded all expectations; while in many parts of the district where this precaution was not taken the vineyards were completely destroyed

ACTUARIAL experience is of distinct value in connection with the application of the statistical method to biological problems; therefore it is of interest to learn from the annual report of the Institute of Actuaries that the mortality investigation, which is being conducted jointly by the Institute and the Faculty of Actuaries, has made material progress under the honorary supervision of Mr. T. G. Ackland. The volume containing the unadjusted data of the annuity experience has already been published. It has been decided to include in one volume the unadjusted data relating to endowment assurances and minor classes of assurance (male and female); and the council report that this volume, forming a second of these series, is now completed, and on the eve of publication. The extensive tables comprising the unadjusted data for whole-life assurances (male lives), are in the printer's hands, and will, when ready, form a third volume of the series. These will be followed, so far as the unadjusted data are concerned, by a fourth and final volume, which will contain the experience of whole-life assurances (female lives). The tables to be included in this final volume are finished, and are in course of being copied for the printer.

WE learn from *Science* that the University of Illinois has fallen heir to the Bolter Collection of Insects. The collection numbers approximately fifteen thousand species, represented by about seventy thousand specimens, besides thirty thousand duplicates not in the systematic collection. This collection, accumulated during the last fifty years by the late Andreas Bolter, is remarkable for the excellence of the material and for the exquisite care with which it has been prepared and arranged. It represents all orders of insects and North America in general, and contains also a considerable amount of exotic material. The gift was made by the executors of Mr. Bolter, in accordance with the terms of his will, conditional upon its maintenance as a unit, under the name of the "Bolter Collection of Insects," in a fire-proof building.

IN the *Irish Naturalist* for June, Prof. R. J. Anderson endeavours to account for the circumstance that in certain breeds of domesticated fowls the keel of the breastbone is crooked. It is somewhat curious to find that these crooked keels occur only in pure bred birds, the ordinary barndoor fowls having the keel straight. After consulting with a number of poultry breeders, the author comes to the conclusion that in-and-in breeding, the nature of the perches, the season, early hatching, defective food and cold may all contribute to the production of the abnormal condition.

IN the Christiania *Nyt Magazin for Naturvidenskaberne*, vol. xxxviii. Pt. 1, Dr. G. Guldberg publishes some observations on the body-temperature of the Cetacea, in which he shows how extremely imperfect is our knowledge of this subject. As he remarks, it is a matter of extreme difficulty to obtain the temperature of living Cetaceans, although this has been taken in the case of a white whale and a dolphin, which some years ago were kept in confinement in a pond in the United States. With the larger whales such a mode of procedure is, however, obviously quite impracticable, and we have accordingly to rely on *post-mortem* observations. The layer of blubber by which all Cetaceans are protected from cold renders the *post-mortem* refrigeration of the blood a much slower process than in most mammals, so that such observations have a much higher value than might at first be supposed to be the case. Indeed, the blood-temperature of a specimen of Sibbald's rorqual three days after death still stood at 34° C. The various observations that have been taken have afforded the following results in *individual cases*:—Sperm-whale, 40° C.; Greenland right whale, 38·8° C.; porpoise, 35·6° C., liver of a second individual, 37·8° C.; common rorqual, 35·4° C.; dolphin, 35·6° C. The average blood-temperature of man is 37° C., and that of other mammals 39° C.; while that of birds is 42° C. The record of 40° C. in the case of the sperm-whale seems to indicate that at least some Cetaceans have a relatively high temperature.

PROF. F. E. NIPHER, in a communication to the Academy of Science of St. Louis, has recently described some experiments that he has made in photographic "reversal," one of his aims apparently being to find a useful method of manipulating photographic plates without the need for the exclusion of light from them. The advantage of such a method is obvious when the experiments incur the possibility of light being accidentally produced, as in electrical work. He exposes the plates to light for a few days before use—"to the light of an ordinary room." The other descriptions of exposures are also vague, the time being given, for example, of camera exposures, but with no record of the lens aperture or indication of the character of the light. It is, therefore, not possible to follow the experiments described in other than a qualitative way. Prof. Nipher has taken street views, Röntgen ray photographs, and "electrographs," on plates that have received preliminary exposures, and developed them by the light, for example, of a sixteen candle-power incandescent lamp, at a distance of from about 1 to 5 feet. The exposure on the object was, in one case, about forty times the exposure that would have been required for making an ordinary negative; the over-exposed and pre-exposed plate giving, of course, a positive image. A good deal of work has already been done in this direction, but the uncertainty of the reversal, and the great difficulty of getting rid of mixed results of reversal and non-reversal, have so far prevented any practical use being made of the possibilities of these methods.

SUCH experiments as Prof. Nipher describes are interesting qualitatively, but before any process of the kind can be safely recommended for general use in cases where it might be advantageous, it will be necessary to determine the range of conditions that can be relied on to give simple, that is, unmixed results, and this can never be done by working with such objects and processes as are described in this communication. We would suggest the use of a series of graduated exposures, with a measurement of the opacities produced, and then the ordinary negative image and the reversed image could both be traced. The character of the reversed image could be judged of, and the range of exposures through which its production could be relied upon could be determined. Until some definite information of this kind is available, experiments in reversal will remain more curious than useful. It appears from Prof. Nipher's communication that he is still pursuing the subject, and we hope that he will succeed in placing the method on a firm foundation.

IN a paper in the *Berichte* of the German Chemical Society, Herr G. Kramer and Herr A. Spilker make the suggestion that an important source of petroleum beds may be the oil which is always diffused through the protoplasm of diatoms.

THE Report of the Botanical Exchange Club of the British Isles for 1898 has just been issued under the editorship of Mr. James Groves. The occurrence of *Stachys alpina* in Gloucestershire is regarded as an undoubted addition to the native flora of Great Britain.

WE have received a prospectus of the "Scientific Roll and Magazine of Systematized Notes," to consist of three volumes of about 500 pages each, which will be supplied to subscribers for 10*s*. per volume, at the rate of one volume a year, commencing in September 1900. The first part will be devoted to the literature of the Schizomycetes. The compiler is Mr. A. Ramsay, of 4, Cowper Road, Acton.

THE Annual Report of the Royal Botanic Gardens, Trinidad, for the year 1899, by the superintendent, M. J. H. Hart, gives evidence of work done in the Gardens in connection with the acclimatisation of foreign economical plants, and the study of diseases of fruits and other crops, with the assistance of the Kew establishment. The *Bulletin of Miscellaneous Information*, from the same Gardens for April, contains, in addition to some natural history notes, a continuation of the descriptive list of West India and Guiana ferns.

A SHORT obituary notice of the late Franz Ritter von Hauer appeared in NATURE for April 13, 1899. A full account of the life and labours of this distinguished geologist has now been published by Dr. E. Tietze (*Jahrb. k.k. geol. Reichs.* Wien, Bd. 49). It is accompanied by a portrait, and by a list of geological papers and books dating from 1846 to 1897.

MESSRS. WILLIAMS AND NORGATE have just published a sixth revised edition of "Prehistoric Times as illustrated by Ancient Remains and the Manners and Customs of Modern Savages," by Lord Avebury (Sir John Lubbock). The first edition was published more than thirty-five years ago.

PROF. PRANTL'S "Lehrbuch der Botanik," upon which Prof. Sydney Vines' "Students' Text-book of Botany" is based, has reached an eleventh edition. The new edition has been revised and enlarged by Dr. Ferdinand Pax, professor of botany, and director of the Botanical Gardens, at Breslau. Mr. W. Englemann, Leipzig, is the publisher.

PROF. VIVIAN B. LEWES has in the press an exhaustive work on acetylene gas—a handbook for the student and manufacturer. The book will contain over 250 illustrations, and comprises a history of acetylene, its preparation, properties and chemical reactions, together with a complete list of legal enactments in full concerning its manufacture, patents, and other important data. Messrs. Archibald Constable and Co. are the publishers.

TWO publications of interest to botanists will be issued from the Clarendon Press before long—the first part of the authorised English edition by Prof. J. B. Balfour of Dr. K. Goebel's "Organography of Plants," and Dr. A. Coppen Jones's translation of Prof. Alfred Fischer's "Structure and Functions of Bacteria." The former brings within reach of English students the only book of recent years upon its special subject; the latter is the only work on bacteriology of similar scope and mode of treatment that has appeared in England since Dr. A. de Bary's "Lectures on Bacteria," a second edition of which appeared in 1887. This translation of Prof. Fischer's "Vorlesungen über Bakterien" should be welcome in pathological laboratories.

THE Orient Company announce that the cruise to Norway, Spitsbergen and Iceland will be repeated this summer. Their steamship *Cuzco*, 3912 tons register, is appointed to leave London on July 3, and to arrive back on August 4. After visiting some of the most interesting Norwegian fiords, the *Cuzco* will proceed to Spitsbergen, thus affording an opportunity of viewing the midnight sun, as for five days and nights after the ship leaves the North Cape the sun will be continuously above the horizon. Thereafter the *Cuzco* will proceed to Iceland, and her contemplated stay there of three days will enable passengers to see some of the most interesting sights in this remote island. The Faroe Islands will also be visited on the way back to London, *viâ* Leith.

THE purification of mercury is frequently necessary in physical and physico-chemical work, the process generally relied upon being distillation *in vacuo*. The apparatus in general use for this purpose, although convenient, has the disadvantage of being somewhat fragile, and requires large quantities of mercury. Some doubts, moreover, have been thrown on the efficacy of distillation as a purifying process, as Victor Meyer, in 1887, showed that traces of foreign metals passed over even after repeated redistillations. According to G. A. Hulett (*Zeitschrift für physikalische Chemie*, xxxiii. p. 611), these traces of foreign metals are carried over mechanically during the bumping of the boiling mercury; and if measures are taken to prevent this bumping, perfectly pure mercury can be obtained in one distillation. Instead of the complicated apparatus of Weinhold, or its various modifications, a slight modification of the arrangement of two distilling flasks, with a capillary tube for admitting air, as commonly employed in organic work, was found to work perfectly.

PROF. RICHARDS, of Harvard, continuing his valuable redetermination of atomic weights, has lately published, in conjunction with Mr. G. P. Baxter, a preliminary paper on the atomic weight of iron. He points out that the value Fe = 56, which is now used, is practically based on work of fifty years since—being Wackenroder's corrected value of Berzelius' result, which was based upon the conversion of metallic iron into ferric oxide. In their preliminary determinations, Messrs. Richards and Baxter have reduced ferric oxide to the metal. The ferric oxide was prepared in the first case from ferric hydrate, which itself was prepared with elaborate precautions from very pure iron ribbon. The mean of two closely agreeing determinations gave Fe = 55·900. In the second case, ferric oxide was prepared with equal care from ferric nitrate. The mean value of five determinations gave Fe = 55·883. Further determinations are promised, but meanwhile the higher value of the older number (Fe = 56) is explained as probably due to one or more of the following causes:—The possible presence of magnetic oxide in the ferric oxide; the possibility of incomplete reduction during the analysis of the substance; the possible presence of alkaline, siliceous or other non-reducible material. At the present stage of the work 55·88 may be taken as the most probable value.

THE additions to the Zoological Society's Gardens during the past week include a Sykes's Monkey (*Cercopithecus albigularis*) from British Central Africa, presented by Mr. C. H. Ambruster; a Barbary Ape (*Macacus inuus*) from Algeria, presented by Mr. R. S. Allen; a Large Red Flying Squirrel (*Pteromys inornatus*) from Northern India, presented by Mr. A. Dudley Yorke; three Goshawks (*Astur palumbarius*), European, presented by Mr. John Simonds; a Little Egret (*Ardea garzetta*) from North-west Africa, presented by Mr. J. H. Yates; an Allen's Porphyrio (*Hydrornia alleni*), captured at sea, presented by Miss Wallace; a West African Python (*Python sebae*) from West Africa, presented by Francis E. Colenso; a Green Lizard (*Lacerta viridis*), European, presented by Miss Mabel A. Heaton; a Common Snake (*Tropidonotus natrix*), British; two Mocassin Snakes (*Tropidonotus fasciatus*) from North America, presented by Mr. W. H. St. Quintin; a Lion (*Felis leo*, ♂) from Kattiwar; a Nylghaie (*Boselaphus tragocamelus*, ♂), two Four-horned Antelopes (*Tetraceros quadricornis*), three Indian Gazelles (*Gazella bennetti*) from India; four Bearded Lizards (*Amphilolurus barbatus*), two Stump-tailed Skinks (*Trachysaurus rugosus*) from Australia, five American Box Tortoises (*Cistudo carolina*), six Stink-pot Mud Terrapins (*Cinosternum odoratum*) from North America, deposited; a Rocky Mountain Goat (*Haploceros montana*, ♂) from British Colombia, two Cunning Bassaris (*Bassaris astuta*) from Mexico, five Gentoo Penguins (*Pygosceles taeniatus*) from the Falkland Islands, a Three-toed Sloth (*Bradypus tridactylus*) from British Guiana, purchased; two Japanese Deer (*Cervus sika*), a Burchell's Zebra (*Equus burchelli*, ♂), born in the Gardens.

## *OUR ASTRONOMICAL COLUMN.*

ROTATION PERIOD OF VENUS.—In the *Astronomische Nachrichten* (Bd. 152, No. 3641), Prof. A. Belopolsky gives the detailed measurements of the photographs of the spectrum of Venus taken during the recent favourable disposition, from which he has been enabled to confirm the short rotation period of the planet.

The spectrograms have been made with the 30-inch refractor at the Observatory of Pulkowa, using two different spectrographs;

one of which was provided with two simple prisms, the other having three compound prisms. The spectra being obtained, the inclination of the spectral lines and the difference of wave-length of the light coming from the two opposite equatorial limbs of the planet is measured, and after corrections being applied for the inclination of the planet's equator to the line of sight, the resulting displacement indicates the equatorial velocity. As the light from the planet is reflected sunlight, the value measured is, of course, double the actual velocity.

The complete measures from fourteen plates taken with the two-prism spectrograph, and from five obtained with the instrument furnished with three compound prisms, are given. The values adopted are the means of measurements of from six to sixteen spectrum lines on each plate.

The photographs were obtained on the evenings of March 25, 30; April 4, 6, 7, 8, 10, 11, 20, 28; May 4, 5, 13, with exposures varying from 7m. to 60m. The angular diameter of the planet varied from 8″·6 to 11″·0. With the 30-inch refractor, of about 40 feet focal length, the linear diameter at the principal focus was 1·2 mm., and this was further reduced by the relative foci of collimator and camera objectives to 0·8 mm. on the photographic plate.

From the difficulty of the determination it is to be expected that the several means should vary for the different plates; but the extreme values given still prove the short rotation period. Taking the diameter of Venus to be 12,700 km., the values of the equatorial velocity ($v$) are as follows, the corresponding time of rotation (T) being placed under each:—

| | | | | | |
|---|---|---|---|---|---|
| $v=$ | 0·7 | 0·5 | 0·462 | 0·45 | 0·3 km. per sec. |
| T= | 15·9 | 22·1 | 24·0 | 24·6 | 37·0 hours. |

The author expresses the hope that the astronomers having the control of the large telescopes at the Potsdam, Lick and Yerkes Observatories will repeat his observations for confirmation or revision.

NEW VARIABLE IN AURIGA.—Dr. T. D. Anderson, of Edinburgh, announces in the *Astronomische Nachrichten* (Bd. 152 No. 3642), the detection of a new variable star in Auriga. It is not charted in the B.D., and has the following position:—

$$\left.\begin{array}{l}\text{R.A.} = \text{6h } 0{\cdot}9\text{m.}\\ \text{Decl.} = +\ 50^\circ\ 14'\end{array}\right\}(1855{\cdot}0)$$

The changes in brightness during April and May 1900 were from 8·3 to 8·8 magnitude.

PHOTOGRAPHIC OBSERVATIONS OF SATELLITE OF NEPTUNE.—In the *Astronomische Nachrichten* (Bd. 152 No. 3642), M. S. Kostinsky gives the particulars relating to a series of determinations of the satellite of Neptune, obtained from measures of photographs taken with a telescope of 13 inches aperture at Pulkowa. Many of the difficulties encountered in the photographic delineation of two neighbouring objects of very different brightness have been previously discussed by the author (*Bull. de l'Acad. Impér. des Sc. St. Pétersbourg*, vol. vii. November 1897). In the present case of Neptune the problem is rendered slightly less difficult by the feeble brightness of the planet and the slow movement of the satellite.

The photographs described were obtained during the period 1899 February 4–March 25, the plates having exposures varying from 20m. to 60m. A table giving the corresponding calculated and observed values shows the method to be very accurate.

## SOME NOTES ON THE LATE PROF. PIAZZI SMYTH'S WORK IN SPECTROSCOPY.

LAMENTING, as we must do, that time has stolen from us a mighty Ajax in the field of science, a sturdy, patient Atlas who through more than half of this fast waning century robustly upheld on his strong shoulders the growing spires and architraves of science's ever-increasing edifice, it is with keenest sorrow that the writer of these notes turns over the ample pages, rich to profusion in details and superb in colour, of the monumental works of spectroscopy left to us by the late Prof. C. Piazzi Smyth, with the nearly hopeless intention of endeavouring to give a short account of some of his most conspicuously important contributions to that branch of science. The late Prof. Smyth was, indeed, no *dilettante* in the intricate and difficult but fertile and alluring byways of science to which his leisure moments were devoted; and he was far from conceitedly or affectedly pedantic in the grasp of science which he brought to bear upon his philosophical investigations. Although these embraced a range of astronomical and meteorological subjects which would singly engage all the energies of most men, and their whole lifetimes to study with success, yet his mastery of the state of science in the questions which he set himself to solve or to explore, was acquired with so much inventive skill, unsparing pains and ardour, as always to make the character of the work which he accomplished in them permanent and thorough. Well accustomed as he was from his youth, and trained from boyhood,[1] to delicate telescopic, angular and micrometrical measurements by eye and hand, he further possessed a gift of great artistic skill in committing to paper, canvas, and even to frescoes, beautiful drawings, photographs and coloured paintings of the scenes of travel which he witnessed, and of sights which clouds, the heavens, or his laboratory experiments disclosed to him. This accomplishment, well illustrated, long ago, by his publication in the Edinburgh *Philosophical Transactions* (vol. xx. pt. iii.) of a scene of darkness on the coast of Norway, near Bergen, during the Total Solar Eclipse of July 1851, contributed again in colours from his original, carefully kept paintings of the scene, together with a similar view of the Zodiacal Light as seen at Palermo in April 1872, to a new illustrated work on astronomy published by Messrs. Cassell and Co. in 1894, led him to leave to others the study of the actinic spectrum-regions with the aid of photography, and to restrict his spectrum-measurements entirely to all that could be seen and measured by the eye alone, of the solar spectrum, or of the characteristic features of gaseous bright-line spectra, in the whole visible portion of the spectrum only.

In his keen perception of all the grand sublimities of law and order by which Nature's works are everywhere controlled and guided and sustained, and in the constant intentness of his mind to seek out these nature's workings, and to promulgate lucidly and clearly his own perceptions and interpretations of them, Kirchhoff's great discovery, in 1859, that the chemical constitution of the sun could be read in its light's prismatic spectrum, constrained him like a spell, as it quickly did many other physicists, to devote much of his leisure time and abilities to spectro-chemical researches. New striking truths were taught in 1860–61 by Sir William Huggins' not less surprising discovery from observations of their spectra, of the gaseous conditions of certain nebulæ, and by Sir David Brewster's and Dr. J. H. Gladstone's majestically mapped separation from the really solar dark lines in the sun's spectrum, of its low-sun, or terrestrial atmospheric lines, soon afterwards distinguished by Secchi, Ångström and the first detector of the "rain-band" near solar D, in America, Dr. J. P. Cooke, and especially by Dr. Janssen's observations among the high Alps of Switzerland and experiments with a long steam-tube in Paris, in 1866–7, into "aqueous-vapour" and "dry-air" telluric lines. Kirchhoff's and Hofmann's first chemical investigation of the solar spectrum was rapidly extended in the years from 1859 to 1868, with tables of metallic and other elementary line-spectra by Huggins and Miller, Mascart, Plücker, Ditscheiner, Van der Willigen, Thalen, Lockyer and others, into a wonderfully novel panorama field of spectrum-analysis, chiefly applicable at first to celestial chemistry and physics, but in such skilled hands as those of Bunsen, Crookes, Reich and Richter, and later of Lecoq de Boisbaudran and other able chemists, to the discovery also of new terrestrial elements. The appearance at Upsala, in 1868, of Ångström and Thalen's classically accurate and chemically expounded "Normal Solar Spectrum" map, with its line-places in a natural diffraction-spectrum order of wave-length progression reckoned in "tenth-metres," or (10)$^{10}$th parts of a metre as scale-units of wave-length,[2] and the detection with spectroscopes in the total solar eclipse of the same year in India, of the hydrogen-flame nature of the sun's red prominences, seen in full sunshine there by Dr. Janssen and almost simultaneously also by Sir J. N. Lockyer in England, afforded to the new study of spectroscopy at once a sound philosophic basis for spectrum-definitions, and a new territory of interesting astronomical investigations in the sun's glowing atmosphere, upon which it was not remiss or slow to grow up in strength and stature, expanding itself largely in new observational, practical and theoretical directions, in the next following interval of ten or fifteen years.

---

[1] Under Sir Thomas Maclear's care, in 1836, at the age of seventeen; at the famous Observatory at the Cape of Good Hope, where, during the last three years, the presence of oxygen was discovered by its line-spectrum in certain southern stars by the indefatigable English amateur astronomer, Mr. F. Maclean; and where both that discovery and another by Sir J. N. Lockyer of the presence of silicium in the same stars, have been confirmed, and made independently by its energetic Director, Sir David Gill, with a noble spectrophotographic 24-inch refracting telescope presented to the Observatory under his own directions and liberal care for its completeness by the same munificent explorer of stellar spectra in the northern and the southern heavens, Mr. Frank Maclean.

[2] It has now become a common usage in spectroscopy, microscopy and molecular physics, to reckon such small quantities as light wave-lengths in a tenfold larger unit than the Ångström one, denoting it by "$\mu\mu$," the thousandth part of "$\mu$," the thousandth part of a millimetre, "mm."

From the graphic mementos which he kept, as we have seen, of the total solar eclipse of 1851, and from his successful attempts, described in 1858 in his well-known and most attractively illustrated volume on Teneriffe, to prove by visits (in that year, and again in 1868) to the Island and Peak of Teneriffe, the practical benefit to be obtained in astronomical observations, of avoiding in great part the atmosphere's absorbing action on the light of stars and planets by establishing observatories on mountain heights, it cannot be doubted that these discoveries with spectroscopes concerning the bright, ruddy light-flakes seen round the sun, or round the moon's disc when the sun is totally eclipsed, and regarding the particular rays of the sun's light which undergo absorption in the earth's atmosphere, would, as important contributions to our extremely circumscribed knowledge of the materials and physical conditions of planetary and stellar atmospheres, greatly impress and interest him.

In the preface of his "Spectre Normale du Soleil," Ångström pointed out that the spectrum of the aurora, as he had frequently observed it in the winter months of 1867-8, consisted almost entirely, as Dr. O. Struve at Pulkova, on hearing from Prof. Ångström of this discovery also confirmed it in May 1868, and as Prof. Ångström had previously found to be the case with the spectrum of very bright appearances of the zodiacal light at Upsala in March 1867, of a nearly solitary bright yellow line. Many exact corroborations of this line's conspicuousness, and detections of several less constant bright and faint auroral lines were thereupon made by observers of a series of fine red auroras which at the time of the marked maximum of sunspot frequency in 1870 appeared during the years from 1869 to 1871. A paper recommending Prof. Swan's well-known blue gas-flame, or blowpipe flame spectrum with its five well-determined line or band-edge positions as a most suitable one for reference in mapping auroral spectra, was sent in 1870 by the late Prof. Piazzi Smyth to the Royal Astronomical Society in London; but owing to his describing the flame-spectrum as Prof. Swan had done in 1856, and as did also Ångström in the introduction to his "Solar Spectrum Atlas" in 1868, as the spectrum of hydrocarbons, or of acetylene, it remained unpublished on account of the doubtfully correct chemical apellation given in the paper to this important set of spectrum-bands. Yet the same chemical origin, describing it as probably that of acetylene, was attributed to this spectrum both by Profs. Liveing and Dewar at Cambridge, and by Ångström and Thalen in their "Spectres des Metalloïdes" at Upsala, in 1875; and Prof. Smyth never felt induced to resign the view which he held in such good company, by the contrary opinion steadfastly maintained by many not less skilled and experienced and at least as chemically well versed spectroscopists, that the blue candle-flame's spectrum of delicately fluted bands was not really due to any chemical compound of carbon with other elements, but to carbon itself in one of the modes of molecular aggregation into which, like the materials of some other metalloids at least, the substance of carbon in its volatilised state is liable, by temperature or by some sufficient chemical or electrical powers of dissociation to be broken up.

Another very similar band-spectrum to the Bunsen-flame one, agreeing in the positions of its two brightest (citron and green) band-edges pretty closely with two corresponding bright band-edges of the latter spectrum, but differing from it throughout in its more numerous remaining bands' positions, and with all its bands evenly shaded, instead of (as in the other spectrum) both fluted and shaded off towards the blue direction, only too often seen mingling with the latter spectrum to some extent in nearly all electrically excited vacuum-tubes, can be very readily produced in its natural purity with ordinary induction-sparks in carbon oxide or di-oxide vacuum-tubes; and it was described on that account, in their "Spectres des Metalloïdes" in 1875, by Ångström and Thalen, and after some hesitation about its possible chemical nature in his first paper on "Gaseous Spectra in Vacuum-tubes under Small Dispersion" in 1880,[1] it was afterwards regarded also by the late Prof. Piazzi Smyth as belonging to carbonic oxide. Appearing as these two spectra do almost ubiquitously as impurities in ordinary gas-vacuum-tubes, their precise discrimination from each other, and the resolution of their many hazy bands into as many ranks of scores upon scores of accurately measured linelets, was a work of exact spectrometry in which the great light-intensities of his vacuum-tubes and the powerful train of prisms finally used by Prof. Smyth for the maps of gaseous spectra which he constructed in 1884,[1] accomplished some of the most wonderfully perfect and beautiful achievements. The much debated experimental evidence as to the chemical origins of these two spectra, moreover, prepared the way for some most embracing views of the modes of production of stellar and celestial spectra, which, besides providing astronomers with the means of classifying stars and the lesser lights of nebulæ and comets methodically, also afforded chemists an imposing outline of problems for consideration, of apparently successive stages of subdivision of the elementary forms of matter from dense into light-atomed elements.

In Sir J. N. Lockyer's hands the condensed spark of a Leyden-jar introduced into the vacuum-tube circuit (which Prof. Smyth never used, having decided to confine himself to weak-spark or low temperature excitations only in his spectrum-measures), supplied a method of transition from the oxy-carbon spectrum in carbon-oxide and dioxide vacuum-tubes, directly to the hydrocarbon or blue gas-flame one,[2] showing that only a rise of temperature was needed, from that of the nearly continuous induction-spark or simple brush-discharge in rarefied gas-tubes, to the vastly hotter disruptive spark (instantly volatilising gold-leaf or thin metallic wires), of a Leyden-jar and air-gap in the outer circuit, to furnish a new spectrum, not, we must conclude, by any chemical change of substance, but by disgregation, it seemed evident, of cool and dense into hot light molecules of pure carbon, which could thus be made at pleasure to give either of these two spectra in succession. The flame, and tube spectra, or the hydrocarbon and carbonic oxide ones are therefore now usually referred to, by Sir J. N. Lockyer, as the "hot carbon" and the "cool carbon" spectrum, respectively.[3] But all the best means that can be used to obtain, on the one hand, an evenly ascending scale of temperature and uniform intensities of action of discharges of the electric arc and spark (the only sufficient known means which can be used to reach the high temperatures demanded), and on the other hand the requisite chemical purity of the substances submitted to spectroscopic examination, are so very liable to unsuspected failures from the many lurking sources of deception which most insidiously waylay and falsify the observations and conclusions, that although, on both sides, these sources of error have been unremittingly sought out and often most startlingly disclosed and very skilfully eliminated, it is difficult to say yet whether the distinctive attributes in which the substances which give the different banded carbon spectra really differ fundamentally from each other, are either, as was at first supposed, simply chemical, or else, according to a subsequent suggestion, attributing to pure carbon spectroscopic properties which are at least not at variance with those of oxygen, hydrogen, sulphur, selenium and phosphorus, of an entirely structural kind; that is to say, gaseously allotropic, or molecularly disgregational under the action of increasing temperature. New discoveries and fresh discussions of these bands must doubtless be awaited before we can be definitely sure to what extent the views expressed by different observers as to the chemically compound or elementary dissociated natures of the material sources of special series of shaded or fluted bands seen in banded carbon spectra can be fully trusted.

Besides the two chief ranks already mentioned, there is another group of two carbon-bands, usually accompanied by a preceding one close-following the gas-flame spectrum's blue beam, near the Fraunhofer rays *h*, H, at the violet confines of the visible spectrum. All three are seen brightly in the spectrum of the electric arc between carbon poles, where the furthest member of this blue, violet, and ultra-violet array produces a just ocularly visible *pharos*-like mass of grey-looking light slightly beyond the spectrum-place of the furthest visible pair of dark lines H, K, of the solar spectrum. This strong outlying pair and its near preceding blue band were referred by Profs. Liveing and Dewar,[1] and also, when he found the two chief bands bright by themselves in his spectrum photographs of the Comet 1881, III., by Sir William Huggins,[2] to cyanogen. But the same strong pair's violet, or first colonnade, between G and *h*, when he first traced it beautifully distinct and bright with the ordinary coil-spark in an end-on marsh-gas vacuum-tube,[3] was coupled on by Prof. Piazzi Smyth, in his "Measures of Gaseous Spectra with High Dispersion," 1884, as it was also grouped by Dr. W. M. Watts in his "Index of Spectra," 1872 (and where Sir J. N. Lockyer classed all these three flutings provisionally together,[4] from a careful survey made in 1880[5] of their deportments, in an unstable-systemed extension, "B," of the "hot carbon's" ordinary set of flutings, "A"), as a sixth or extra fluted-band transcending in refrangibility all the five commonly seen ones of the "hydrocarbon," or blue gas-flame series.

[1] Edinburgh *Philosophical Transactions*, vol. xxx. (1883), pp. 99, 104. In a letter to NATURE (vol. xx. p. 75), in May 1879, on "End-on Vacuum-tubes brought to bear on the Carbon and Carbohydrogen question," the late Prof. Piazzi Smyth also adopted at first without reserve the view of this spectrum that it is produced by carbon simply.

[1] "Micrometrical Measures of Gaseous Spectra under high Dispersion," Edinburgh *Philosophical Transactions*, vol. xxxii. Pt. 3 (1886). The end-on vacuum-tubes used in these measures and in those of the earlier paper, were devised by the late Prof. Smyth himself, as described in a paper, "End-on Vacuum-tubes in Private Spectroscopy," read before the Royal Scottish Society of Arts in 1879. The eminent spectroscopist of Ghent, in Belgium, Dr. van Monckhoven, had, however, invented and used such tubes a few years earlier. An ingenious arrangement of electrodes which he applied to them in 1882 (one electrode at the foot, and one at the summit of each upright leg), for passing two discharges of different strengths, either simultaneously or alternately through the connecting capillary tube, in a research on the effects of temperature and pressure in widening gas-spectrum lines, was described in an interesting paper by Dr. van Monckhoven, in *Comptes rendus*, vol. xcv. (*2me semestre*, 1882).

Six of the seven main lines of the blue band of this set were marked as measured lines distinctly, by Prof. Piazzi Smyth, in a hazy glow of light immediately following the fourth, or blue band of his "High Dispersion Spectrum" Paper's full-length map of the "hydrocarbon" spectrum, but as considerably weaker lines than those of the violet or "marsh-gas" band. As the blue band, however, is in fact the weakest one of a group of bands which only the exceedingly hot flame of cyanogen, or the intense heat of the electric arc, or jar-spark usually produces, its exact indication there, precisely in its natural inferiority of strength to the violet array, and with only one line missing of its seven, at the beginning of the hazy glow, is a speaking testimony to the faithful accuracy of the late Prof. Piazzi Smyth's spectrum records, as well as to the watchful care with which all the spectra which he mapped were guarded against contaminating admixtures of interloping gas-spectra; since with the modest 2–3 inch sparks which he was content to use, of a simple induction coil, nothing but the lamp-like brightness of the Salleron and Casella end-on tubes examined, and the chemical purity of the contents of those used in taking final spectrum measures, could have been expected to show the weakest of the three "cyanogen" bands so equally free from other spectrum-glares, and almost as sharply well-defined in position, as its bright violet companion tier of "marsh-gas" lines was seen and measured.

The fifth (faint violet) band—or the latter part of it—seen under high dispersion to contain only hazy linelets, with no strong lines or sharp-edged flutings, is the only visible light-beam in the Bunsen-flame spectrum which Sir J. N. Lockyer seems willing to admit,[6] can be described correctly as a "hydrocarbon" band; and in his splendid series of discriminations of celestial spectra, that brightest portion of the Bunsen flame's violet band forms the whole system of spectroscopic bands which in those analyses of celestial spectra is usually indicated as characteristically denoting hydrocarbon radiation. Two small bands, or fluted line-groups, however, sometimes occur also in this unstable violet, or "Carbon-B" region, of which one is classed by Sir J. N. Lockyer together with the *pharos*-like band beyond H, K, as an invariable accompaniment (much more refrangible than the four "Carbon-A" bands) of the "hot-carbon" spectrum. This small three-lined band falls exactly in place and width on the Bunsen-flame spectrum's fifth, or violet band's preceding zone of weak hazy light, as the late Prof. Piazzi Smyth, in his full-length map and micrometric measures of that spectrum pictured it, surrounding the place of the violet line $H\gamma$ almost as closely as its bright following "hydrocarbon" light-zone surrounds the dark solar line G's position, with a curiously prominent solitary bright line in the dark partition space between them. A fairly satisfactory explanation of this fifth band's construction might thus, with no material need of any reconciling adjustment to the "Carbon-B" band's line-places, be extracted from the Edinburgh spectrum record, by supposing the first and second portions of its divided light-field to belong really to different radiant sources, and to be due, independently of each other, respectively to "hot carbon" and to "hydrocarbon gas's" incandescence. But the near agreement in position between the flame-band's feeble front-domain of shapeless light-haze, and the "hot carbon's" small three-ribbed fluting lacks far too much from being well affirmed by exact coordinations to be any certain evidence of a real spectroscopic or physical connection; and the weak preceding portion of the violet flame-band has thus been very appropriately consorted by Sir J. N. Lockyer with the following bright portion of this violet haze-band, as belonging both together to the hydrocarbon spectrum.[1] Another small violet-region band was traced by Sir W. Huggins in the spectrum of the Comet 1881, III., where it lay between the violet and the ultra-violet "cyanogen" bands, a little beyond *h* towards the line H of the solar spectrum.

Among this "Carbon-B" *suite* of bands, suspected by Sir J. N. Lockyer at an early stage of his spectroscopic observations of the sun, in 1874, to have counterparts in the dark lines of the solar spectrum, the strong *pharos*-like ultra-violet fluting's delicate train of bright lines and linelets was at length photographically proved by Sir J. N. Lockyer, in 1878,[2] to coincide precisely with a close-packed orderly array of faint, exceedingly fine dark lines at the same place in the solar spectrum; and the same coincidence of about thirty serrations of this band in ten Ångström's wave-length units, with as many exactly corresponding ripplings of light and darkness at the ultra-violet confines of the sun's visible spectrum was again very abundantly well proved by Profs. Trowbridge and Hutchins at Hartford, U.S., in 1887.[3] It was also pointed out by Profs. Liveing and Dewar at the close of the second of their above-quoted papers, in 1880, on the "Spectra of Compounds of Carbon with Hydrogen and Nitrogen," that a fluted ultra-violet band in the spectrum of the cyanogen-flame, of which they photographed many in an ultra-violet region extending far beyond this grey one's position, exactly coincided in spectrum-place with the remarkably fluted ultra-violet dark band P, in the solar spectrum. After Sir W. Huggins and Padre Secchi had independently detected the "hydrocarbon's" or low gas-flame's bands in the spectrum of Winnecke's Comet, in 1868, and some ten or twelve comets in as many following years were found to show the same bands in their spectra,[4] together with occasional traces of the oxy-carbon or "cool-carbon" spectrum, a far wider range of the "hot" and "cool carbon" bands was presently discovered for them by Sir J. N. Lockyer among the spectra of celestial bodies, and in his "Researches on the Spectra of Meteorites," in 1887,[5] and in the Bakerian Lecture to the Royal Society on a "Suggested Classification of the various Species of Heavenly Bodies,"[6] the low gas-flame's or hot carbon spectrum's bands were clearly shown to exhibit themselves, with rarer excrudescences of cool carbon bands, not only in comets, but alike in sun-like and fluted, and bright-line and temporary stars, and even in nebulæ, the aurora, and sometimes in lightning-flashes, as a sort of torch-light glow of colliding meteorites, condensed meteoritic swarms, and electrically gasified and illumined meteoritic dust, throughout the universe.

It surely needed then only the recent discovery by Prof. G. E. Hale and his coadjutors, Mr. W. S. Adams and Prof. Frost, in

America,[1] with the giant telescope of the Yerkes Observatory's enormous power, that the green and citron hydrocarbon's chief band-lines can be observed dark on the photosphere at the sun's edge, and close by, bright in the chromosphere to a height from the sun's edge which they estimated not to exceed 1″ of arc, or about 500 miles, to completely ratify the foregoing views that those low gas-flame's fluted bands are produced by carbon vapour at an exceedingly high temperature; and fully to justify the first observers in England and America of the presence of carbon in the sun, in the opinion which they independently expressed, that the temperature of the glowing region of the sun's atmosphere where this carbon vapour is produced and made to incandesce, must certainly approach nearly to, and at the same time not much exceed, that of the electric arc.

Carbon substance furnishes yet another known form of gaseous spectrum, which consists only of a few sharp bright lines, quite free from bands of shaded light, or flutings; and this linear form of its spectrum may be pretty certainly ascribed to carbon vapour in its simplest molecular, perhaps even monatomic, state of aggregation, since it is only obtained by heating carbon in a condensed electric spark to the highest possible artificial temperatures. No indications, however, of carbon's occurrence at this exceedingly high temperature in any celestial spectra, appear as yet to have been met with. Although no gaseous spectra produced at such high temperatures as those of the condensed electric spark were spectroscopically measured by the late Prof. Piazzi Smyth, yet a depiction of this carbon spectrum as it was first seen in the Leyden-jar spark between carbon poles by Ångström in 1863, and as it was represented by Ångström and Thalen in their "Spectres des Metalloïdes" in 1875, is given with the line-spectra of common air, hydrogen, nitrogen and oxygen and of vapour of mercury, by different authors, in the Plate of full-length spectra of his "High Dispersion Spectrum" Paper of 1884, by the late Prof. Smyth, to compare with his own measurements of low temperature spectra of the same elementary gases or their compounds. The map of the carbon line-spectrum given by Ångström and Thalen shows a spectrum-field extremely bare of lines, but terminated, at its two ends, by two very bright ones, a red, closely double line almost coincident with Fraunhofer's C, or $H\alpha$, and a violet one close-following G and the violet hydrogen line $H\gamma$, and like the hydrogen-lines appearing to be easily widened into a diffuse, broad line by taking the spark in gases at increasing pressures.[2]

A faint single line near E, and two groups of three and four moderately bright, pretty close-packed lines near the beginnings of the two brightest (green and citron) flutings of the Bunsen-flame, or "hot-carbon" band-series, are all the remaining visible portions of this spectrum figured, as they had excellently observed and studied it, by Profs. Ångström and Thalen. But the latter two isolated line-groups appear to fit on remarkably well to the view already apparently borne out and substantiated by what precedes, that with rising temperatures and increasing disgregation of carbon-vapour molecules, the interval between the beginnings of the green and citron flutings becomes wider in passing from the "cool" to the "hot" carbon-band series. For while those band-beginnings are respectively at $\lambda = 519·70$ and 560·75 (distance = 41·05μμ) in the cool, or oxy-carbon set, and at $\lambda = 516·40$ and 563·34 (distance = 46·94μμ) in the hot, or hydrocarbon set of bands, the front-lines of the "Excelsior" Carbon-spectrum's (as the late Prof. Piazzi Smyth poetically termed it), or still hotter and more broken-up carbon-vapour molecules' two small solitary line-groups, are at $\lambda = 515·05$ and 569·41, in Ångström and Thalen's Table of these carbon lines; both shifted again slightly in position in the same left and right directions as before, and with the interval between them again increased a little, now, from its last measures, 41·05 and 46·94, to 54·36μμ.

But a most industrious explorer, and a describer and recorder unsurpassed in the skill of his depictions of the surprising beauties of all this rich domain of matter's spectroscopic radiations, we must again here grieve to note, has passed away. Besides his already-mentioned extremely perfect measurements of "gaseous spectra," the late Prof. Smyth's published spectrum-maps and spectroscopic writings comprised long descriptions too of not less than five full series of measurements with high dispersion, in southern skies, and with great magnifying powers, of the dark lines of the solar spectrum.[1] These graphic solar-spectrum maps and those of the "gas-spectra," and separate papers treating also of the oxygen-gas spectrum singly, and of the dark line group "*b*" in the solar spectrum by itself,[2] together form a lasting store of precious materials for spectroscopic study too variously instructive and often suggestive of interesting theoretical deductions from their well-recorded details, to be here dealt with shortly and concisely. It is with a sense of doing only very partial justice to the exceedingly high merit and scientific value of those other important spectrum records and researches, that as much space as could be accorded to these short notes has been devoted here to pourtraying only the increasing cosmical significance and the widely-spreading applications in spectroscopic astronomy, of his valuable investigations of the ordinary forms of carbon spectra. In his effectual unravelling of the mazy linelet systems of those familiar spectra's bands, a plain and simple law of sequence in the linelets' spectrum-places was disclosed, which some years later also proved the proper clue to elicit order from the complex-looking linelet structures of the dark absorption-bands, "A" and "B" (both due to oxygen in our terrestrial atmosphere), at the red end of the solar spectrum. Although those shaded groups' constructions were only perfectly made known at last in 1893, by Mr. G. Higgs, of Liverpool,[3] from the beautiful figures of them given in his then published "Photographic Studies of the Solar Spectrum," yet the drawings of those bands in Prof. Smyth's Madeira and Winchester Solar Spectrum Plates in 1881 and 1884, only second to Mr. Higgs' photographs in their clear discriminations and accurate positions of the bands' details, would have certainly afforded ripe enough materials to establish at least the major portions of their simple featured laws of linelet sequence by themselves, if they had been searchingly examined, and carefully enough discussed and studied for the purpose.

Further examples of the same simple law of linelet intervals in such "shaded" bands (where each distinguishable *suite* or tier of linelets exhibits simply a fixed and uniform excess or growth of interval—of each *suite's* own amount or proper measure—in every pair of adjoining lines, over that of its immediately preceding line-pair, as the rank of lines advances from the brighter to the dimmer region of the shading) occur, moreover, not only in the brightest, green, but also in the citron and the blue band-figures, very plainly, of Prof. Smyth's full-plate "high dispersion" maps of those three most notable light-ridges in the "carbon oxide" (or "cool carbon") spectrum. Another interesting indication of line-systems also can be traced in his full-length mapped array of the four then known low temperature lines of oxygen, three of which he discovered to be finely triple, and to which he contributed three more just similarly triple lines. Two Balmer's series of three lines each can be pretty certainly distinguished in this strikingly peculiar group of six mapped triplets, converging approximately to a nearly common progression-head, or series-limit, at about $\lambda = 430$ μμ. Possibly these two line-sequences which his much extended range and finely multiplied line-features of the ordinary tube-spectrum of oxygen appear to show, may have been already recognised and fittingly comprised by Messrs. Kaiser and Runge among the many such line-series which they have found indications of in the spectrum-field of oxygen. But these and many more such philosophical results may be looked for to be richly gleaned and brought to light by coming years' discussions of the minute and copious information which with Mr. T. Heath's skilful assistance in their draughtsmanship and computations, is lucidly unfolded in Prof. Smyth's noble works of well resolved and accurately measured ranks of lines both in the solar and in gaseous spectra. In those several sound and stalwart *opera*

[2] This widening of the carbon violet line to a "broad band" at $\lambda = 4272$ (Ångström, 4266·0) is very distinctly recorded in Dr. W. M. Watts' "Index of Spectra," 1872, "Carbon-Spectrum, No. IV."; where the groups and single lines, $\alpha$, $\beta$ (*plus* the two next lines), $\gamma$, and $\iota$, compose together Ångström and Thalen's line-spectrum of pure carbon. With four or five exceptions, all the many lines contained in the several other line-groups besides these, in the same Carbon-Spectrum Table, can, however, be readily identified with lines of the oxygen line-spectrum mapped by Ångström and Thalen on the same Spectrum-Plate ("Spectres des Metalloïdes," Upsala *Nova Acta*, vol. ix. 1875) with their line-spectrum of carbon, and also with lines in Dr. Schuster's map (*Philosophical Transactions* of the Royal Society, 1879) of the line-spectrum of oxygen.

*magna* of spectroscopic explorations, we may surely feel convinced that after-times will neither fail to be gratified with results of scientific consequence, nor find it easily possible to overlook the great accessions made by the late Prof. Piazzi Smyth to spectroscopic science, by his boldly-planned recourses to, and ingeniously contrived employments of, great optical power and very high dispersions.

A. S. Herschel.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Oxford.—At a meeting of the Junior Scientific Club, held on Friday, May 18, Dr. Mann gave a *résumé* of the history of the nerve cell from Malpighi's and Leeuwenhoek's time up to the present. He showed the advance due to the introduction of new methods, viz. chromic acid by Hannover, Golgi's and Ehrlich's methods, and the Picro-corrosive sublimate method of the author. Ehrenburg in 1833 discovered the nerve-cell, Beale in 1863 the nerve-fibril, Flamming and Nissl the basophil substance of the cell, which, as Mann was the first to show, becomes used up during functional activity. Hohngren's observations on material fixed by Mann's methods had demonstrated the universal occurrence of intracellular lymph channels in nerve-cells. Finally it was suggested that the basophil substance (Nissl's bodies) should rather be regarded as the homologues of Zymogen granules than as reserve material in the strict sense of the word.—Mr. A. D. Darbishire (Balliol) showed a number of living crustaceæ by microscopic projection on to a transparent screen.

Cambridge.—The honorary degrees in law, science, and letters, were conferred in presence of a large and brilliant assemblage on June 12. Prof. Langley was unable to arrive from America in time to be present, but the American Ambassador, Lord Rosse, Sir Benjamin Baker, Sir Walter Buller and Prof. Poincaré attended, and received a cordial welcome. The following are the speeches delivered by the Public Orator, Dr. Sandys, in presenting to the Vice-Chancellor the under-mentioned recipients of honorary degrees for distinction in science:—

### The Right Hon. the Earl of Rosse, LL.D.

Assurgit proximus Universitatis Dubliniensis Cancellarius, cuius pater munere eodem ornatus atque etiam Regiae Societati praepositus, Hiberniâ in mediâ instrumentum ingens stellis observandis olim construxit; cuius de fratre autem, navis celerimae inventore sollertissimo, omnibus notum est "quo turbine torqueat" undas. Ipse famam inter peritos adeptus est, non modo de lunae calore subtilius inquirendo, sed etiam stellarum nebulis remotissimis (ut Aristophanis a Nubibus aliquantulum mutuemur) ὄμματι τηλεσκόπῳ observandis. Habetis exemplar domus praeclarae scientiarum amore conspicuae, cuius caput dignitatis Academicae heres dignissimus exstitit. Qui abhinc annos octo Universitatis suae inter ferias saeculares tot honores in alios contulit, hodie fortasse nobis ignoscet, quod honos ipsi olim debitus praecepto illi Horatiano nimium paruisse visus est:—"nonum prematur in annum."

### Sir Benjamin Baker, Sc.D.

Quantum miratus esset historiarum scriptor, Gaius Cornelius Tacitus, si providere potuisset fore aliquando, ut Caledoniae fretum, Bodotriae nomine sibi notum, duobus deinceps pontibus immensis iungeretur! Quantum miratus esset historiae pater ipse, Herodotus, si audivisset fore aliquando, ut vir quidam, ab insulis Britannicis sibi prorsus ignotis oriundus, fluminis Nili aquas redundantes duplici mole et aggere magno coerceret et Aegypti regioni immensae irrigandae conservaret! Operis utriusque magni conditorem magnum hodie praesentem contemplamur, qui non pacis tantum triumphis contentus, velut alter Archimedes, etiam Martis tormentorum inventor et machinator admirabilis exstitit. Atqui ne Martis quidem inter opera pacis causam revera deseruit; etenim scriptoris antiqui de re militari monitum non ignotum est:—"qui desiderat pacem, praeparet bellum."

### Sir Walter Lawry Buller, Sc.D.

Coloniae nostrae remotissimae, Novae Zealandiae, inter decora conspicua numeratus, adest hodie vir regionis illius indigenarum linguae imprimis peritus, cui, propter merita eius egregia, gratiae saepenumero publice sunt actae. Adest vir qui etiam regionis illius avibus summâ curâ describendis atque arte eximiâ depingendis opus magnum dedicavit. Quantum autem liberalitati eius etiam nostra Academia debeat, Musei nostri parietes, avium et animalium aut prorsus aut prope extinctorum exemplis ornati, satis clare loquuntur. Ergo quem ipsa Regina, quem et Gallia et Germania et Italia honoribus cumulaverunt, eundem etiam nosmet ipsi, tot munerum non immemores, laudis nostrae diademate decoramus.

### M. Henri Poincaré, Sc.D.

Sequitur scientiarum Academiae Gallicae socius illustris, scientiae mechanicae caelestis inter Parisienses professor insignis, societatis Regiae Londinensis inter socios exteros olim numeratus, astronomorum denique a societate Regia numismate aureo nuper donatus. Quantam laudem meritae sunt investigationes illae subtilissimae, de aestuum maritimorum natura universa, de molium liquidarum sese rotantium aequilibrio, de planetarum denique et satellitum cursu vario, ad exitum felicem ab hoc viro perductae! Studiorum mathematicorum in utrâque provinciâ, et analyticâ et physicâ, propter scientiae suae prope infinitam varietatem inter principes numeratus, quam egregie nuper ostendit quantum provinciae illae vicinae invicem inter sese deberent! Quam pulchre studiorum suorum voluptatem cum artis musicae et artis pingendi voluptate comparavit! Quam ingenue mathematicam physicam confitetur novam quandam linguam desiderare; linguam cotidianam nimis exilem, nimis ambiguam esse, quam ut aliquid tam delicatum, tam subtile, tam varium, possit exprimere. Et nos idem hodie libenter confitemur: viro tali pro meritis eius tam variis laudando lingua nostra vix sufficit. "Conamur tenues grandia."

The Knightsbridge Professorship, vacant by the resignation of Dr. Sidgwick, will be filled up on Saturday, June 30. Candidates are required to send their names to the Vice-Chancellor by June 25.

Mr. G. F. C. Searle has been appointed a university lecturer in experimental physics; and Dr. G. H. F. Nuttall, university lecturer in bacteriology and preventive medicine.

The first award of the Raymond Horton-Smith Prize has been made to Mr. A. B. Green, for his M.D. thesis on amyloid disease.

Mr. W. A. Macfarlane-Grieve, M.A., Oxford and Cambridge, of Impington Park, has offered to the University a farm of about 145 acres near Cambridge, free of rent till Michaelmas 1909, for the purposes of the Department of Agriculture. This handsome offer has been gratefully accepted on behalf of the Board of Agricultural Studies, to whom the management of the experimental farm is assigned.

The *University Reporter* for June 12 contains an interesting report on Mr. W. W. Skeat's exploring expedition to the Malay provinces of Lower Siam.

The Right Hon. A. J. Balfour, M.P., will deliver the inaugural address to the students of the Vacation Courses, arranged by the University Extension Syndicate, at 12 noon on Thursday, August 2.

The Arnold Gerstenberg Studentship in moral philosophy for graduates in natural science has been awarded to Mr. T. J. Jehu, of St. John's College, who holds a Heriot Fellowship in geology from the University of Edinburgh.

The Mathematical Tripos list is unusually short this year. The sixteen wranglers are headed by Mr. J. E. Wright of Trinity, Mr. A. C. W. Aldis of Trinity Hall being second wrangler. An Indian student, Mr. Balak Ram of St. John's is fourth; and Miss W. M. Hudson of Newnham College, sister of the senior wrangler of 1898, is bracketed eighth wrangler. Miss E. Greene, also of Newnham, is equal to tenth. St. John's claims five of the wranglers, Trinity four, Clare two.

In Part II., the bracketed senior wranglers of last year, Mr. Birtwistle of Pembroke, and Mr. Paranjpye of St. John's, are placed with two others in the first division of the first class.

Mr. Chamberlain, Chancellor of Birmingham University, has received a letter from Mr. W. H. Foster, Apley Park, Bridgnorth, offering a donation of 2000*l.* towards the endowment fund.

Mr. J. G. Clark, whose death is announced from Worcester, Massachusetts, was a generous promoter of the interests of education in the United States. By his efforts the Clark University at Worcester, Mass., was founded "to increase human knowledge and transmit the perfect culture of one generation to the ablest youth of the next; to afford the highest education and opportunity for research." He gave a close study to the subject of the higher education, and was anxious to include in his proposed University the best features to be found in institutions in America and elsewhere. At the foundation of the University in 1889, Mr. Clark gave it an endowment of one million dollars, to which he added a like amount later on. By his death, the institution receives his magnificent library of rare and costly books. Clark University is perhaps unique among the educational institutions of the United States. It is devoted entirely to post-graduate studies, and recently celebrated its tenth anniversary.

As announced last week, a series of festivities began at Cracow, on June 7, in commemoration of the 500th anniversary of the foundation of Cracow University. A Reuter correspondent states that a large number of men of science, including representatives of most of the European universities and colleges, attended the celebration. The Austrian and foreign investigators went in procession on Thursday morning to the Church of St. Mary, where a Papal Brief in reference to the celebration was read. The graves of the founders of the University were visited and wreaths deposited upon them. At the special commemorative meeting subsequently held, speeches in Latin were delivered by Prof. Tarnowski, the rector, and Dr. von Hartel. An illuminated address was presented by a deputation from Oxford University. The proceedings terminated with the distribution of the diplomas of honour to those upon whom the honorary degree of doctor has been conferred.

THE new Directory of the Board of Education, South Kensington, containing regulations for establishing and conducting science and art schools and classes, has just been published. Many of the regulations have been modified, more particularly those referring to administrative matters and practical work. The syllabus of practical mathematics has been revised, but the subjects remain much the same as were prescribed in last year's syllabus. A syllabus of an advanced stage of practical mathematics has been added. The syllabus of mineralogy has been slightly modified and recast. The laboratories in a School of Science are to be available for preparation work by students of the school beyond the school hours of the time-table. Courses of work for Schools of Science in rural districts have been added. The obligatory subjects of the elementary course for men are:—(1) mathematics; (2) chemistry (with practical work); (3) physiography (Section I.) or elementary physics (with practical work); (4) biology (Section I.) or elementary botany (practical work may be in the field or garden); (5) drawing, practical geometry, or practical mathematics. Manual instruction in its application to workshop and garden must also form part of the course, which is intended to cover two years. The elementary course for women in Schools of Science differs slightly from the foregoing. Physics and chemistry are optional for the second year, and hygiene may be taken instead of botany. Practical mathematics is not included. Separate advanced courses of work are prescribed for men and women who have passed through the elementary courses. Managers of schools are now allowed the option of having the grant for practical chemistry in the advanced course assessed by the inspector or on the results of examination in the advanced stage. The announcement made last year that examinations in the elementary stages of science and art subjects will only be held upon special application, in which case a fee for each paper asked for will be charged, is ratified. This probably means the abolition of examination in the elementary stages; for apparently nothing can be gained by arranging for the examination of candidates.

---

## *SOCIETIES AND ACADEMIES.*

### LONDON.

**Physical Society,** June 8.—Dr. J. H. Gladstone, F.R.S., Vice-President, in the chair.—A paper on the magnetic properties of alloys of iron and aluminium (Part ii.), by S. W. Richardson and L. Lownds, was read by Dr. Richardson. Experiments have been made to ascertain in what way the hysteresis loss between given limits of the field strength is connected with the temperature for an alloy containing 3·64 per cent. of aluminium. The experiments show that the hysteresis loss attains a maximum value at a temperature considerably higher than the temperature of maximum induction. The changes produced in the magnetic properties of the alloy by heating and subsequent cooling have also been investigated. The properties depend largely on the previous history of the specimen, but there does not appear to be any essential difference between the behaviour of the alloy during heating and cooling (except near the temperature of minimum permeability). Experiments have also been conducted on the abrupt change in the permeability that takes place at a temperature of about 650° C. The conclusions arrived at are as follows:—(1) The hysteresis loss at first diminishes as the temperature rises. It then increases and reaches a maximum at about 550° C. On further heating it falls off rapidly, and is negligible at 700° C. (2) The magnetic properties of the specimen depend largely on its previous history. (3) There is no essential difference between the behaviour during heating and cooling except near the temperature of minimum permeability. (4) An abrupt increase in the permeability takes place at about 650° C. during heating, followed by an equally abrupt diminution on further heating. (5) This abrupt change is more marked with falling than with rising temperatures. (6) Continued heating and cooling diminish the permeability. (7) The curve connecting temperature of minimum permeability and percentage of aluminium is a straight line. (8) The microscopic examination of the specimens shows the presence of crystals. Prof. S. P. Thompson asked if the specimens had been kept for any length of time at a high temperature, because crystals changed and grew in metals at temperatures even far below their melting points. Prof. Reinold asked if any specimens had been examined where the crystalline structure had not been observed. Mr. Blakesley asked if any explanation of the orientation of the crystals could be given. The chairmain said it was difficult to know exactly what substances were being dealt with. They might be pure alloys or mixtures of two or three alloys with iron or aluminium. Dr. Richardson in reply said the crystals might be dissolved in nitric acid and analysed, but at present he did not know their composition.—Mr. W. Campbell then read a note on crystallisation produced in solid metal by pressure. In the preparation of sections of tin, particles cling to the file and, if allowed to remain, tend to tear the surface of the metal. The effect is not immediately noticeable, but on etching the polished surface there appear, besides the usual structure of the tin, lines of much smaller crystals with irregular boundaries but possessing different orientation. The effect is only superficial because it can be removed by polishing. The same behaviour is noticed in some alloys, and it would thus appear that the pressure of a file is sufficient to cause a metal or an alloy to rearrange itself. Prof. S. P. Thompson suggested that the effect might be due to local heating caused by tearing rather than to pressure. Mr. Campbell said that the effect was not due to the heating of the file, because if the file were kept perfectly clean no crystals formed. Prof. S. P. Thompson asked if scratching the surface with a diamond produced crystallisation. The author said he had tried with a sharp knife without success, but cutting with a blunt chisel produced crystallisation along the chisel mark.—A paper on the viscosities of mixtures of liquids and solutions was read by Dr. C. H. Lees. Three formulæ have been suggested for expressing the viscosity of a mixture in terms of the percentages and viscosities of its constituent parts. The first of these represents the viscosity as being the sum of a number of terms, each one of which is the product of the percentage of any constituent and its viscosity. The second formula represents the logarithm of the viscosity in a similar manner, and the third one the reciprocal. None of these formulæ represent the viscosity of a mixture with closeness. The author suggests a formula in which the *m*th power of the reciprocal of the viscosity of a mixture is equal to the sum of a number of terms, each one of which is the product of the percentage of any constituent, and the *m*th power of the reciprocal of the viscosity of that constituent. This formula gives satisfactory agreement, and, moreover, leads to Slotte's formula for the variation of viscosity with temperature.—The secretary read a note from Prof. Wood on an application of the method of striæ to the illumination of objects under the microscope. The object chosen was powdered glass immersed in cedar oil of the same refractive index. The glass particles were almost invisible under ordinary conditions of illumination. The illuminating system was then arranged as follows:—A screen, bounded by a straight edge, was placed in front of an incandescent gas lamp, so as to cut off half of the mantle, and give a source of light bounded by one perfectly straight edge. A small lens of very short focus was placed below the stage as close as possible to the object. The lamp was at a distance of six feet, and the light reflected from the mirror was brought to a focus by this lens, passing through the object on its way. An image of the lamp was formed in space and viewed by the microscope. A little strip of thin brass, with a carefully cut straight edge, was fastened to the stand carrying the bull's eye condenser, and moved into position between the objective and object so as to cut off the flame-image with the exception of a narrow thread of light along the straight edge. The brass screen must be in the plane of the flame-image, with its edge parallel to the straight edge of the flame. The brass was then advanced over the flame until nearly all the light was cut off. Upon lowering the microscope until the object was in focus, and carefully advancing the brass strip until practically all the flame-image was cut off, it was found that the glass particles suddenly appeared with great sharpness, showing as distinctly as if in air. Two photographs of glass in oil were shown, one taken with ordinary illumination, and the other by the Schlieren-Methode.

**Geological Society**, May 23.—J. J. H. Teall, F.R.S., President, in the chair. — The igneous rocks of the coast of County Waterford, by F. R. Cowper Reed. The first part of this paper is devoted to a discussion of the field-evidence, as shown by the coast-sections from Newtown Head to Stradbally. The igneous rocks there exposed are divided into the following five categories :—(*a*) The felsitic rocks ; (*b*) necks of non-volcanic materials ; (*c*) the basic sills and vents ; (*d*) intrusions of dolerite ; (*e*) intrusions of trachyte, andesite, &c. ; (*f*) intrusions of other types. In regard to the age of the rocks, there appear to have been two main periods of volcanic activity : the first, in Ordovician times, was marked solely by outpourings of a felsitic nature ; the second, post-Ordovician but pre-Upper-Old-Red-Sandstone, was characterised by a succession of several distinct types of igneous rocks. The relative age of some of the peculiar types of intrusive rocks is indicated in the paper in those cases in which it can be determined. That those rocks which are later in date than the folding of the Ordovician are older than the Upper Old Red Sandstone is shown (1) by the unconformity of the Upper Old Red Sandstone ; (2) by the fact that the latter rock does not contain any interbedded igneous rocks ; and (3) by the absence of felsitic or other intrusive rocks from the Old Red Sandstone of the district. The second part of the paper is devoted to petrological notes on the different rock-types.—On a new type of rock from Kentallen and elsewhere, and its relation to other igneous rocks in Argyllshire, by J. B. Hill, R.N., and H. Kynaston. [Communicated by permission of the Director-General of H.M. Geological Survey.] A rock originally described by Mr. Teall from Kentallen is used by the authors as a type round which they group a peculiar series of basic rocks discovered in several localities. The rocks consist essentially of olivine and augite with smaller amounts of orthoclase, plagioclase and biotite, while apatite and magnetite are accessory. The peculiar feature of the rocks is the association of alkali-felspar with olivine and augite, and the group is related to the shonkinite of Montana and the olivine-monzonite of Scandinavia.

**Anthropological Institute**, May 29.—The President in the chair.—Prof. Oscar Montelius, of Stockholm, made a communication on the earliest communications between Italy and Scandinavia. Beginning with the evidence derived from the discovery, in Denmark and Central Europe, of bronze bowls and other objects of Roman date, coming from the workshops in Italy, as similar to examples found at Pompeii and elsewhere, he traced the active and copious intercourse thus demonstrated, step by step backwards in time through the period of early Greek commerce at the beginning of the Iron Age in the Mediterranean, into the later and earlier Bronze Age ; and illustrated his conclusions by a variety of classes of objects, which though originally of Italian origin and manufacture are found widely distributed in Central Europe, in Denmark and in Sweden ; and can be shown by numerous examples to have been imitated by the bronze working industry of these northern areas. Among these objects, he regarded the attenuate sword-hilts and the bucket-like *situloe* as demonstrating this intercourse for the early centuries of the first millennium B.C. ; the transversely-grooved sword-hilts, and the simple bow-fibula as proving the same for the later half of the second millennium, corresponding with the Mycenæan Age in the Mediterranean ; the triangular dagger-shaped blades, and the imitations of open spiral torques and bracelets, as representing the earlier half of the same ; and the rude hour-glass shaped types of cups and vessels as carrying the same argument back beyond the date 2000 B.C.—The paper was followed by a discussion.

### PARIS.

**Academy of Sciences**, June 5.—M. Maurice Lévy in the chair.—The eclipse of the sun of May 28, 1900, at Paris, by M. Lœwy. The observations were interfered with by the state of the sky.—Total eclipse of May 28, by M. J. Janssen. An account of the work done in Spain by observers from the Observatory of Paris.—On the calorific equilibrium of a closed surface radiating outwardly, by M. Émile Picard.—Observation of the solar eclipse of May 28 at Marseilles and Algiers, by M. Stéphan. As the atmospheric conditions were extremely favourable at these two stations, good observations of the times of contact, and of the corona and solar protuberances, were taken.—Observations of the partial eclipse of the sun of May 28 at the Observatory of Bordeaux, by M. G. Rayet.—Observations of the planet (FG) (Wolf-Schwassmann, May 22), made with the large equatorial of the Observatory of Bordeaux, by MM. G. Rayet and Féraud.—On the curve of rifling in fire-arms, by M. Vallier.—The formation of the coal-measures, by M. Grand'Eury. In contrasting the two theories current for explaining the formation of coal deposits, the drift theory and the peat bog theory, the author cites instances in which, from his own observations, both influences must have been at work simultaneously.—The total eclipse of the sun of May 28 observed at Hellin, in Spain, by M. Hamy. The observations, which were entirely successful, include seven photographs of the corona. The characteristic green line of the corona, although falling within the sensitive region of the orthochromatic plates employed, gave no trace of impression in the spectrum photographs.—The total eclipse of the sun of May 28. Observations made at the Observatory of Algiers, by M. Ch. Trépied. The plan of operations included observations of the four contacts, visual study of the corona, photography of the partial eclipse, photography of the corona and of the spectrum of bright lines in the chromosphere, the photography of the spectrum of the corona, and thermo-actinometric observations. Under the very favourable atmospheric conditions, all the results were good, the only failure being in the attempt to photograph the spectrum of the corona.—On the solar eclipse of May 28, by MM. Meslin, Bourget and Lebeuf. Results of observations made at Elche. The photograph of the spectrum of the corona, obtained with a Rowland concave grating, shows circles corresponding to the lines H, K and G.—Observations of the eclipse of the sun of May 28, by M. de La Baume Pluvinel. Nine photographs of the corona were taken, but the instrument set apart for the special study of the coronal line gave no result.—On the proportion of polarised light in the solar corona, by M. J. J. Landerer. The proportion found was 0·52.—The eclipse of the sun of May 28 observed at Besançon, by M. Gruey.—The partial eclipse of the sun of May 28, at the Observatory of Lyons, by M. Ch. André. The scheme of operations included the comparison of the time of direct observation of contact with that made by projection upon a white screen, and the examination of the dark line noted in the eclipse of 1882.—The solar eclipse of May 28, observed from a balloon, by Mdlle. D. Klumpke.—On the theory of the moon, by M. H. Andoyer.—On the congruences of circles and spheres which are multicyclic, by M. C. Guichard.—On divergent series, a correction of an earlier note, by M. Le Roy.—On the decomposition of continued finite groups, by M. Edmond Maillet.—On the integration of the equation $\Delta u = fu$, by M. J. W. Lindeberg.—On the electrical state of a Hertz resonator in activity, by M. Albert Turpain.—Researches on the existence of a magnetic field produced by the movement of an electrified body, by M. V. Crémieu. According to Maxwell, a charged electrified body in motion should produce magnetic effects, the magnitude of which can be calculated from the charge and velocity of the moving body, and experiments by Rowland in 1876, and Rowland and Hutchinson in 1889, gave results in agreement with Maxwell's views. Lippmann, applying the principle of the conservation of energy to Rowland's experiment, shows that magnetic variations ought to produce a movement in electrified bodies situated within the field, but experiments by the author would appear to show that such an effect is not produced. A repetition of Rowland's original experiments, under conditions more favourable to accuracy, also leads the author to conclude that the motion of an electrified body produces no magnetic effect.—Measurement of the quantity of electricity and of electrical energy distributed by continuous currents, by MM. A. and V. Guillet.—On a mode of decomposition of some metallic chlorides, by M. Œchsner de Coninck. Gold can be completely removed from solutions of auric chloride by filtering through animal charcoal; solutions of the perchlorides of platinum and iron are also decomposed on filtration through animal charcoal. No such decomposition could be observed with the chlorides of nickel, cobalt, manganese, zinc, copper and magnesium.—On the conditions of stability of rotatory power, by M. J. A. Le Bel. It is found that at temperatures of 100° or thereabouts, many optically active bodies tend to lose their rotatory power by racemisation; on the other hand, if the asymmetric radicals grouped round a central atom are increased in volume, the stability is increased.—On the dihydroxylates, by M. de Forcrand.—Addition of hydrogen to acetylene in presence of copper, by MM. Paul Sabatier and J. B. Senderens. A mixture of hydrogen and acetylene passed over reduced copper at a temperature of 130°—200°, reacts readily, forming ethane, ethylene and other hydrocarbons, no acetylene remaining unchanged if the hydrogen is in excess.—On the copper and mercury organo-metallic compounds of diphenylcarbazone.—On acidimetry, by M. A. Astruc. A study of the behaviour of isethionic, sulphanilic, meconic and mellic acids with indicators.—On a new species of subterranean Isopod, *Caecosphaeroma Faucheri*, by MM. Adrien Dollfus and Armand Viré.—Gregarinæ and intestinal epithelium, by MM. L. Léger and O. Duboscq.—On the animal fossils collected by M. Villiaume in the carboniferous strata near Nossi-Bé, by M. H. Douville. The whole of the carboniferous strata in the region of Nossi-Bé belongs to the Upper Lias, and is to be classified with the carboniferous strata of the same age in the north of Persia.—On the vegetable fossils collected by M. Villiaume in the carboniferous beds in the north-west of Madagascar, by M. R. Zeiller. The conclusions drawn are in harmony with those drawn by M. Douville in the previous paper from a study of the animal fossils.—The volcano of Gravenoire and the mineral springs of Royat, by M. P. Glangeaud.

---

## DIARY OF SOCIETIES.

### *THURSDAY*, June 14.

Royal Society, at 4.—Election of Fellows.——At 4.30.—Some New Observations on the Static Diffusion of Gases and Liquids, and their Significance in certain Natural Processes occurring in Plants: H. T. Brown, F.R.S., and F. Escombe.—The Electrical Effects of Light upon Green Leaves (Preliminary Communication): Dr. A. D. Waller, F.R.S.—The Nature and Origin of the Poison of Egyptian Lotus (*Lotus Arabicus*): W. R. Dunstan, F.R.S., and T. A. Henry.—The Exact Histological Localisation of the Visual Area of the Human Cerebral Cortex: Dr. J. S. Bolton.—Data for the Problem of Evolution in Man. V. On the Correlation between Duration of Life and the Number of Offspring: Miss M. Beeton, G. U. Yule, and Prof. K. Pearson, F.R.S.—The Diffusion of Ions produced in Air by the Action of a Radio-active Substance, Ultra-violet Light and Point Discharges: J. S. Townsend.—On an Artificial Retina and on a Theory of Vision, Part I.: Prof. J. C. Bose.

Mathematical Society, at 5.30.—Some Multiform Solutions of the Partial Differential Equations of Physical Mathematics and their Applications, Part ii.: H. S. Carslaw.—Some Quadrature Formulæ: W. F. Sheppard.—Notes on Concomitants of Binary Quantics: Prof. Elliott, F.R.S.—Extensions of the Riemann-Roch Theorem in Plane Geometry: Dr. Macaulay.—On the Invariants of a certain Differential Expression connected with the Theory of Geodesics: J. E. Campbell.—On the Constants which occur in the Differentiation of Theta Functions: Rev. M. M. U. Wilkinson.—On the Transitive Groups of Degree $n$ and Class $n-1$: Prof. W. Burnside, F.R.S.—The Invariant Syzygies of Lowest Order for any Number of Quartics: A. Young.—Further Notes on Bilinear Forms: T. J. I'A. Bromwich.

### *MONDAY*, June 18.

Royal Geographical Society, at 8.30.—The Country between Lake Rudolf and the Nile Valley: Captain M. S. Wellby.

### *TUESDAY*, June 19.

Zoological Society, at 8.30.—On the Significance of the Hair-slope in certain Mammals: Dr. Walter Kidd.—On the Anatomy of *Bassaricyon alleni*: F. E. Beddard, F.R.S.—Observations on the Habits and Natural Surroundings of Insects and other Animals, made during the "Skeat" Expedition to the Siamese Malay States: Nelson Annandale.

Royal Statistical Society, at 5.—The Defence Expenditure of the Empire: The Right Hon. Sir Charles W. Dilke, Bart.

Mineralogical Society, at 8.—On Conchite, a New Variety of Calcium Carbonate: Miss Agnes Kelly.—On the General Determination of the Three Principal Indices of Refraction from Observations made in any Arbitrary Zone: G. F. Herbert Smith.—On Monazite from Tintagel: H. L. Bowman.—On the Oxidation of Pyrites by Underground Water: Dr. J. W. Evans.—Petrological Notes: G. T. Prior.—A Quantitative Determination of the Action of Hydrochloric Acid and Soda Solution on the Enstatite and Felspar of the Mount Zomba Meteorite: L. Fletcher, F.R.S.

### *WEDNESDAY*, June 20.

Geological Society, at 8.—On the Skeleton of a Theriodont Reptile from the Baviaans River (Cape Colony): Prof. H. G. Seeley, F.R.S.—On Radiolaria from the Upper Chalk at Coulsdon (Surrey): W. Murton Holmes.—Fossils in the Oxford University Museum. IV. Notes on some Undescribed Trilobites: H. H. Thomas.

Royal Meteorological Society, at 4.30.—Rainfall in the West and East of England in Relation to Altitude above Sea-level: William Marriott.—Description of Halliwell's Self-recording Rain Gauge: Joseph Baxendell.

Royal Microscopical Society, at 8.—Demonstration on the Structure of some Palæozoic Plants, with Sections of the Plants shown by the Lantern: W. Carruthers, F.R.S.

### *THURSDAY*, June 21.

Royal Society, at 4.30.

Linnean Society, at 8.—On some Scandinavian Crustacea: Dr. A. G. Ohlin.—The Subterranean Amphipoda of the British Islands: Chas. Chilton.—On certain Glands of Australian Earthworms: Miss Sweet.—Notes on Najas: Dr. A. B. Rendle.

Zoological Society, at 4.30.—The Gigantic Sloths of Patagonia: Prof. E. Ray Lankester, F.R.S.

Anatomical Society (Owens College, Manchester), at 10.30.—Lantern Demonstration on the Comparative Anatomy and Histology of the True Cæcal Apex—the Appendix Vermiformis: Dr. R. J. Berry.—Lantern Demonstration of some Surface Markings of the Calvaria, and their Significance: Prof. Dixon.—Lantern Demonstration of Microphotographs of the Maturation Stages in the Ovum of Echinus: Dr. T. H. Bryce.—Some Points in the Anatomy of the Digestive System: Prof. Birmingham.—(*a*) Two Cases of Absent Vermiform Appendix; (*b*) A Specimen showing Direct Continuity between the Long External Lateral Ligament of the Knee-joint and the Peroneus Longus Muscle; (*c*) A Supernumerary Bone in the Carpus connected with the Trapezium: Prof. Fawcett.—A Note on the Genital Apparatus of the Jerboa: Dr. Armour.

Chemical Society, at 8.—Ballot for the Election of Fellows.—Notes on the Chemistry of Chlorophyll: Dr. L. Marchlewski and C. A. Schunck.—Researches on Morphine, I.: Dr. S. B. Schryver and F. H. Lees.—A New Series of Pentamethylene Derivatives, I.: Prof. W. H. Perkin, jun., F.R.S., Dr. J. F. Thorpe, and C. W. Walker.—Experiments on the Synthesis of Camphoric Acid. III. The Action of Sodium and Methyl Iodide on Ethyl-dimethyl-butanetricarboxylate: Prof. W. H. Perkin, jun., F.R.S., and Dr. J. F. Thorpe.—On the Oxime of Mesoxamide and some Allied Compounds: Miss M. A. Whiteley.—The Oxyphenoxy- and Phenyleneoxy-acetic Acids: W. Carter and Dr. W. T. Lawrence.—(1) The Condensation of Ethyl α-Bromo-isobutyrate with Ethyl Malonates and Ethyl Cyanacetates: α-Methyl-α′-isobutylglutaric Acid; (2) Methylisoamylsuccinic Acid, II.: Dr. W. T. Lawrence.

### *FRIDAY*, June 22.

Physical Society, at 5.—Notes on Gas Thermometry: Dr. P. Chappuis.—A Comparison of Impure Platinum Thermometers: H. M. Tory.—On the Law of Cailletet and Mathias and the Critical Density: Prof. J. Young, F.R.S.

Anatomical Society (Owens College, Manchester), at 10.30.—Note on the Configuration of the Heart in a Man and some other Mammalian Groups: Dr. C. J. ## *THE REMINISCENCES OF A VETERAN OF SCIENCE.*

*Erinnerungen aus meinem Leben.* By A. Kölliker. Pp. x + 399; with 7 plates, 10 text figures, and portrait of the author. (Leipzig: W. Engelmann, 1899.)

THE memoirs of the venerable Professor of Anatomy at Würzburg will interest a wide circle of readers in this country, whether amongst the older generation of scientific men, whose privilege it has been to know the author as a genial friend and colleague, or amongst the juniors in rank and years, to whom the name of Kölliker has been one which from their youth upwards they have learnt to respect as that of a great leader in scientific thought and discovery. Many of the latter class may, perhaps, learn from this book, for the first time, how much modern zoology owes to its author. So rapid has been the advance of biological science in the latter half of the nineteenth century, and so great is the interval, judged not by time, but by the progress of knowledge, which separates the science of to-day from that of fifty years ago, that there is always considerable danger of the merits of those who have grown grey in the ranks of science being overlooked or insufficiently realised by the younger generation. Students are taught at an early stage in their career facts or principles which seem so well established or even self-evident, in the light of current knowledge, that it is quite an awakening to find that the man who first enunciated them is still living in our midst. To give one instance, a student of zoology is taught, probably in the very first lecture he attends, the distinction between Protozoa and Metazoa based upon the essentially unicellular nature of the individual in the former sub-kingdom. If he reflects at all on the matter, a truth so obvious and so easily demonstrated will seem to him one which has been recognised by mankind perhaps from a remote antiquity. Yet it was Kölliker who first, in 1845, pointed out the existence of unicellular animals, and brought forward the Gregarines as instances, and who later, in conjunction with von Siebold, expressed the opinion that all the Infusoria, with the exception of such forms as the Rotifers, consisted of single cells. In a further work upon *Actinophrys* this conclusion was extended to the Rhizopods, and so a great generalisation was established, the truth of which is now never called in dispute.

Quite apart, however, from the great interest which these memoirs possess from the scientific point of view, their appearance at the present time is welcome for other reasons. At a period of strained political relations, when our country appears isolated in aims and sympathies from the rest of Europe, when international antipathies and prejudices seem in a fair way to spread from the official to the personal sphere, it is a refreshing change to read the narrative of one who was a frequent and a welcome visitor in our midst. To judge, at least, from the prevailing tone of this book, its author is no "Britenfresser." He refers constantly with warmth, we might say with affection, to the hospitality of his many friends in this country and to the pleasant times he spent in their homes, feelings which, we can be sure, were as warmly reciprocated by those about whom he writes.

The book is divided into two parts, the one personal, the other scientific. Part i. contains a general account of his life, with details of his many scientific and other journeys, and a brief account of his relations to various learned societies. Part ii. may be described as a *catalogue raisonnée* of his works, and is a marvellous record of many-sided scientific activity. His publications, amounting to nearly 250 memoirs, are arranged under the headings of histology, anatomy, physiology, embryology, evolution, comparative anatomy and zoology, and other miscellaneous items. Under each subdivision is given a historical account of his work, its main results, the ideas which guided him, and the conclusions which he upheld. Here much will be found of great value to the student—using the word in its widest sense—which cannot be dealt with adequately within the limits of a brief review. We turn, therefore, with greater interest to the personal narrative set forth in Part i.

Rudolf Albert Kölliker was born at Zürich on July 6, 1817. His boyhood and schooldays were passed in his native town, and he was intended at first for a business career, but, fortunately for science, this idea was given up, and he entered Zürich University, in 1836, as a medical student. At the University his attention was first given to botany, a subject in which he had as fellow-student his intimate friend, Carl Nägeli, and his first publication (1839) was a list of the phanerogams of Zürich. Besides other medical and scientific courses he attended the stimulating lectures of Oken on zoology and nature-philosophy. In 1839 he spent a semester at Bonn, and attended lectures on surgery and kindred subjects which were still delivered in Latin. He next went to Berlin for three semesters, from 1839 to 1841, a period which he describes as a turning-point in his life, since here he came under the influence of two great masters, whose courses he attended—namely, Johannes Müller and Jakob Henle. Of the former, he writes: "the comprehensive outlook by which he connected forms widely separated, and showed what they had in common, was especially stimulating and, for me, new." From Henle on the other hand, he received his first introduction to the cell-theory of Schwann, and his attention was directed to the structure of the animal body in a number of lectures and demonstrations which he describes with enthusiasm:—

> "Now when the youngest medical student is acquainted with all this and much more from pictures of all kinds, and the facts concerning the minutest structure of the body are in every one's mouth even at school, it is not easy to realise the impression made upon the student at that time by the first sight of a drop of blood, a ciliated lining, a section of bone or a striped muscle fibre, and the impress of these experiences remains permanently in the memory."

Besides Müller and Henle, he attended many other eminent teachers at Berlin, including Ehrenberg and Remak. From the latter he received his first demonstrations of the embryology of the chick. In spite, however, of his ardent medical and scientific pursuits, he found time to attend lectures on ethics and Hegelian philosophy. It was a result doubtless of Henle's influence that his first anatomical memoir was an investigation upon spermatozoa, published in 1841, with which he took his degree of philosophy at Zürich in 1841, and of medicine at Heidelberg in 1842. In the former year he passed his State examination, of which he records the following contretemps:—

> "I, who had at my fingers' ends the finest ramifications of the cranial nerves, the structure of the auditory labyrinth, of the eye, the brain, and so forth, was unable to answer a question on the portal vein."

This is an experience which will assuredly come home to many, and while hence eliciting our sympathies, will at the same time afford no slight consolation to those who reflect on the subsequent achievements of the unfortunate examinee.

In 1841 Kölliker was appointed assistant to Henle, who had received the chair of anatomy at Zürich. In the following year he took a trip to Naples, where he made the acquaintance of Delle Chiaje, Costa and Krohn, and occupied himself with, amongst other things, his well-known studies on the development of Cephalopods. In 1843 he became docent at Zürich, and was prosector to Henle from 1842 until the latter's promotion to Heidelberg in 1844. Henle's chair was then divided into one of anatomy and one of physiology, and Kölliker received the latter; but in 1847 he accepted a call to Würzburg. His departure from Zürich, which was much regretted there, was largely caused by political intrigues in the faculty of the University.

At Würzburg he occupied, at first, the chair of comparative anatomy, but in 1849 he received that of anatomy, which he has now filled for more than fifty years, in a way that needs no praise. The names of many of the most eminent professors of anatomy in Germany, past or present, are to be found in the lists of his pupils or assistants, of whom it is only necessary to mention C. Gegenbaur, Fr. Leydig, R. Wiedersheim, H. Grenacher and Th. Eimer. In 1848 he was associated with von Siebold in founding the *Zeitschrift für wissenschaftliche Zoologie*, of which famous journal he is still one of the editors.

The accounts of his many journeys are compiled, for the most part, from letters written by him at the time to his relations or friends. There is much of interest to be found in them, especially in his visits to England. His first acquaintance with this country was made in 1845, and renewed on many subsequent occasions. In his letters he gives his impressions of England and English life. He quickly made for himself a large circle of intimate scientific friends, amongst whom he mentions, particularly in his earlier letters, the names of Todd, Bowman, Grant, Sharpey, Edward Forbes and Wharton Jones. His time in London seems to have been very well filled up, as he writes in one letter that in the last twelve days he had gone through nine dinners and two breakfasts, some of which do not seem to have been very entertaining. "I took part yesterday in a fearfully wearisome dinner, enough to kill one (etwas ganz totmachendes)," he writes; and further on he complains that "these everlasting dinners, lasting from 6 to 11 o'clock, have taken me *en grippe*, as the French say; but what can one do?" But in other cases he seems to have been happier. In London he is presented at Court, and finds that "the Queen is really pretty, and Prince Albert is also a handsome man." On the eve of his departure, he expresses himself almost as much at home in London, in spite of its size, as in Zürich, and considers it "very interesting, often pleasant, but for the most part fatiguing." He visited this country again in 1850 and 1857, on both of which occasions he spent some, or most, of the time in Scotland, where he became intimately acquainted with John Goodsir and Allen Thomson, and in London with Queckett. His letters from Scotland to C. Th. von Siebold contain some interesting remarks about English science and scientific men.

> "The English doctors and physicians are, above all, practical men, and all that pertains to the theoretical side takes with them the second place. This is partly owing to the fact that the English are a people occupied chiefly with commerce, but only partly so; the chief cause of the phenomenon in question is the fact that science does not hold the place it deserves in popular estimation, nor is it supported by the Government in such a way that a man who devotes himself to it can be free from care."

This is the reason, he thinks, why so many men full of enthusiasm for science remain in practice, and finally lose themselves in it; while others regard theoretical studies merely as an advertisement to gain them more clients, since practice in England is golden, and procures for the practitioner a position which contrasts vividly with that of a professor.

> "I know only three anatomists and physiologists in England," he adds, "who do not practise—namely, Owen, Sharpey and Grant, of whom Owen alone has a position at all equal to his merits."

In 1850 he also paid a short visit to Oxford, where he met Acland, Strickland and J. V. Carus, but found little that attracted him, and he returned, he tells us, to noisy but infinitely more stimulating London, well satisfied that he was not obliged to spend all his days in "this most peculiar of all university towns."

Space does not permit of reference to the many interesting personal reminiscences or amusing incidents which recur so frequently in this book, especially that detailed in two letters on p. 162, of which we lose nothing by its being to a large extent veiled in the obscurity of the English tongue. It can only be said that the book affords delightful reading, and gives pleasing glimpses of a warm-hearted and charming personality as well as of a great man of science. E. A. M.

## DIFFERENTIAL EQUATIONS.

*Theory of Differential Equations.* By A. R. Forsyth, Sc.D., F.R.S. Part i. (1890). Pp. xiv + 340. Part ii. (1900). Pp. xii + 344, and x + 392. (Cambridge: At the University Press.)

ALTHOUGH these volumes contain more than a thousand pages, it would be premature to express an opinion upon the plan and proportions of Prof. Forsyth's work as a whole; so much of his vast subject still remains unrepresented. Thus the reader will find nothing, except incidentally, of the theory of partial differential equations; and, what is more remarkable, the subject of ordinary linear equations has been reserved for a future volume. However, the two parts which have now been published are so far complete in themselves that it is possible to give some account of their contents, and to appreciate, to some extent, the author's method and point of view.

Part i. treats of exact equations and the problem of Pfaff. Of the two chapters on exact equations it is enough to say that they contain an excellent summary, with well-chosen examples, of the various methods which have been suggested; the most interesting part is that which deals with Mayer's very remarkable extension of Natani's procedure.

The rest of vol. i. is devoted to Pfaff's problem. A chapter on the history of the problem is followed by ten others, which give, in the order of their discovery for the most part, the principal results of Pfaff, Jacobi, Natani, Clebsch, Grassmann, Lie and Frobenius. This plan has its advantages, especially for those who wish to become familiar with the literature of the subject; and mathematical experts will duly appreciate the service which Prof. Forsyth has done them. But if we look at the result as a text-book for mathematical students, it is a question whether the course taken is the best one. A chapter which is an excellent guide to a reader who has before him the original book or memoir upon which it is based, may be simply puzzling to a student unfamiliar with the subject, and unable to refer to the primary sources. It is doubtful, for instance, if any one who has not mastered the *Ausdehnungslehre* will be able to appreciate the chapter on Grassmann's method; and in the same way, the chapters on tangential transformations and Lie's method will not, we fear, do much, in themselves, to arouse an interest in Lie's magnificent discoveries. It is unfortunate that Prof. Forsyth's exclusively analytical attitude has prevented him from utilising Lie's geometrical or quasi-geometrical conceptions. It is quite true that intuitional methods require to be controlled by strict analysis; but they often vivify a mathematical theory in a very instructive and fruitful way. Take, for instance, the question of the "integral equivalent" of the differential relation $Pdx+Qdy+Rdz=0$, where P, Q, R are functions of $x, y, z$. If we take $x, y, z$ as ordinary Cartesian co-ordinates, this relation associates with any point $A(x, y, z)$ a flat pencil of elementary line-elements, concurrent at A, and lying in a definite plane $P(\xi-x)+Q(\eta-y)+R(\zeta-z)=0$. Thus we may take the "content" of the differential relation to be either a manifold of $\infty^1$ line-elements, or of $\infty^3$ plane-elements. If the given relation is an "exact equation" $d\phi=0$, the integral $\phi=c$ gives us a family of $\infty^1$ surfaces, each of which contains $\infty^3$ line-elements of the content and $\infty^2$ plane-elements of it. Moreover, every continuous curve made up of line-elements lies (in general) on one of the integral surfaces $\phi=c$, and the line and plane elements of the surfaces exhaust the corresponding elements of the content. These considerations justify us in saying that $\phi=c$, with $c$ an arbitrary constant, is a complete integral equivalent of the differential relation. But in a case like $xdx+zdy-ydz=0$, we cannot construct an integral equivalent of this kind; and the question arises, what integral equivalent, if any, exists, and what will be the nature of its equivalence? To Prof. Forsyth, this is a purely analytical question; he simply inquires what functional relations connecting $x, y, z$ are consistent with the given relation. Of the degree and nature of the equivalence to be expected he says very little; and the gist of what he does say is relegated to a note on p. 250. The geometrical theory at once suggests the possibility of constructing "integral curves" by linking line-elements of the content; a complete integral equivalent may be conceivably constructed by a system of $\infty^3$ integral curves together exhausting all the line-elements of the content, or again by $\infty^2$ integral curves, each with $\infty^1$ associated plane-elements of the content. As an example of the latter kind of integral equivalent, the system of lines

$$x=a, \quad y=bt, \quad z=t$$

where $a$, $b$ are arbitrary constants, and $t$ is a variable parameter, are integral curves derived from the content of $xdx+zdy-ydz=0$; and if with each point $(a, bt, t)$ we associate the elementary flat-pencil which lies in the plane $a(x-a)+t(y-bz)=0$, we have a complete integral equivalent, all the elements of the content being taken into account. If we take the two analytical relations $x=a$, $y=bz$, involving arbitrary constants only, we get, it is true, a kind of integral equivalent; but this is not complete, in any sense analogous to the complete integral of an exact equation.

Part ii. deals with ordinary equations, not linear; and the point of view is almost entirely that of function-theory. The coefficients in the equation are analytical functions, in Weierstrass's sense; and the main problem is that of discussing the functional nature of the dependent variable or variables. The discussion is necessarily based upon the work of Cauchy, Briot and Bouquet, Weierstrass and Fuchs; the analysis is simple enough in essence, but the details, unfortunately, are unavoidably lengthy, and tend to be monotonous, owing to the necessity of considering different cases and establishing a set of typical forms. The results are so important that the student is bound to make himself familiar with them; but the judicious reader will do well to use his privilege of skipping. The fact is, that the demonstrations fall naturally into a very few types; and it is as profitless to study every one of them minutely as to attempt a detailed examination of every kind of singularity of an algebraic curve. There are, of course, many points in the analysis which cannot fail to arouse interest and admiration; for instance, the use of a dominant function in proving the existence-theorem, and the employment of a sort of extended Puiseux diagram in the applications.

Then, again, there are those surprisingly general and definite results which have been deduced, almost as corollaries, from this somewhat unattractive analytical theory. It must suffice to refer to Painlevé's theorem (ii. p. 211), that the points of indeterminateness of every integral of a single equation of a certain very general type are *fixed points* determined by the differential equation itself; and to the result established by Bruns (iii. p. 311 and following), that every algebraic integral of the differential equation of the problem of three (or more) bodies can be constructed algebraically from the long-known classical integrals. But the reader will find other results of almost equal interest due to Poincaré, Fuchs, Picard and others. The reaction of the Weierstrassian function-theory upon other branches of analysis, and in particular upon the problems of celestial mechanics, is truly remarkable.

It is to be hoped that the publication of Prof. Forsyth's work will make English mathematicians better acquainted with current research on the subjects with which he deals. The value of his treatise for really competent readers is evident, and needs no commendation. But we may, perhaps, regret that he has not more definitely considered the interests of the rising generation. It is most important that new ideas and recent methods should be introduced to young men of ability while their minds are keen and susceptible; and their interest is seldom aroused in the first instance by a treatise which aims at being exhaustive. To take an example in point; few readers, we imagine, to whom the subject was new, would persevere in the study of Lie's great work on transformation-groups; yet what mathematical student could fail to be delighted with his lectures on differential equations with known infinitesimal transformations, as edited by Dr. Scheffers?

No doubt the task of writing an introductory, and thoroughly didactic, treatise on the modern aspects of this theory is very difficult; more so, very likely, than the one to which Prof. Forsyth has applied himself. The selection, combination and assimilation required would demand a great deal of care and judgment; a certain lightness of touch would also be desirable, and this is not easy to maintain after a course of reading in the extremely ponderous memoirs which are so often found in the literature of the subject. But a work of this kind might do more than the most conscientious handbook to encourage a living interest in the theory of differential equations. There is some appearance of a tendency to over-elaboration in English treatises presumably written for students; to authors as well as to lecturers may be commended the maxim "Above all, do not be dull." G. B. M.

## *OUR BOOK SHELF.*

*Origin and Character of the British People.* By Nottidge Charles Macnamara. Pp. 242; 33 figures. (London: Smith, Elder and Co., 1900.)

MR. MACNAMARA seeks, in a small compass, to indicate the origin of the component parts of the British people, and to account for the differences of local moral character by proportionate inheritance from the original races, all of which are assumed to have their mental and moral peculiarities as fixed as their physical characters. He believes that the Iberians, as he prefers to call the Mediterranean or Afro-European race, formed the primary stock from which the existing inhabitants of Great Britain and the West of Europe are derived; and that they are the modified descendants of Palæolithic man. The tall fair Aryans originated in Western Asia. The pioneer migration of the Aryans into Europe formed the Cro-Magnon race; then came the dolmen-builders, the South Mediterranean branch extending from the Amorites to the "fair Libyans"; the migrants into Central Europe mixed with the brachycephals and constituted the "Celts." A distinct northern migration formed the Teutonic Aryans.

The author also believes that dolmens and long barrows are everywhere the work of the Aryan race. The prehistoric tall brachycephals of Northern Europe were a branch of the Northern Mongolian or Turanian race. The short dark brachycephals of Central Europe brought the art of working in bronze from Asia, presumably from Burmah. The Formorians of Ireland were Iberians; in North-west Ireland are still to be found descendants of the Northern Mongoloid race; the Firbolgs were Celtic Aryans or dolmen-builders. The Southern Mongoloids arrived in the bronze age; these are the Tuatha de Danann. A second invasion of Aryan Celts, or Milesians, arrived in Ireland also during the bronze age. This abstract gives a fair idea of the scope and views of the author.

*The Geography of the Region about Devil's Lake and the Dalles of the Wisconsin.* By Prof. R. D. Salisbury and Mr. W. W. Atwood. Pp. x+151. (Madison, Wisconsin: Geological and Natural History Survey, 1900.)

THIS is the first number of an "Educational Series" to be published by the Wisconsin Geological and Natural History Survey. The region to which attention is now particularly called is in the south-central part of Wisconsin, and it is of interest because it well illustrates many points in the geographical evolution of land-surfaces. It comprises an undulating plain chiefly of Potsdam Sandstone, with some areas of magnesian limestone, and with a northern and southern range of bold quartzite hills. The southern range rises from 500 to 800 feet above the surrounding land, or up to 1600 feet above sea-level, and in the bottom of a deep gap, which divides this range, lies Devil's Lake. This is a lake which, in glacial times, occupied an enclosure between the ice on the one hand and the quartzite ridge on the other: a gorge which originally was the work of a pre-Cambrian stream. The melting of the ice supplied abundant water, and the lake rose perhaps 90 feet above its present level. In this and in many other cases the irregular deposition of glacial drift gave rise to many depressions without outlets, in which surface-waters collected after the ice had disappeared. Few of these lakes now remain in the region, but Devil's Lake, which is more than a mile in length and half a mile wide, occupies an unfilled portion of an old river valley, isolated by great morainic dams from its surface-continuations on either hand. Streams originate beyond these dams. The "Dalles" are sandstone cliffs which form a gorge along the Wisconsin River for a length of about seven miles, and a depth of 50 to 100 feet. The effects of weathering by atmospheric agents, and of erosion by the river, are well exhibited, and the views remind us of the rock-scenery along the Eden near Corby Castle.

The volume, which, with its index, extends to 151 pages, is in reality an essay on the origin of scenery treated from a geological point of view. The authors deal with the pre-Cambrian history of the quartzite, from its origin in loose sand to its uplift and deformation; and they deal similarly with the other strata. They contribute also a fairly full account of the phenomena of the Glacial period, and of the work of rain and rivers. Numerous excellent photographic representations of the scenery are given, including views of various natural arches, tors, and needles.

*Monistische Gottes- und Weltanschauung.* Von J. Sack. Pp. viii + 278. (Leipzig: Engelmann, 1899.)

IN Herr Sack's view all particular existences are modes of one spirit-substance—God. He calls this doctrine monism, and not pantheism, because he thinks the latter not incompatible with polytheism. Be this as it may, the distinguishing mark of his thesis is that it works to an Hegelian doctrine of being along the lines of a naturalistic theory of becoming that might satisfy Mr.

Spencer. The result is a form of vitalism. The movement which is to be found in the inorganic world is not merely continuous with, but synonymous with life and consciousness. Matter is not only the revelation of spirit, but body and spirit are one and the same. His method, which consists simply in the assumption that human spirit is an *analogon* of the world-principle, will not bear this conclusion. And his superstructure is rather in the air.

In his view of evolution there is nothing novel. It is, of course, teleological. Its real dynamic, as opposed to its formal occasions, is the all-inclusive being as principle of organisation. The working of this is elucidated quite after the manner of Mr. Spencer, by what Herr Sack oddly calls "antinomies"—viz. the antithesis of individuality and community, and the like.

It is when he comes to deal with art, morals and religion that Herr Sack is most at home. These are man's adumbrations of the contents of the intellectual intuition of the universal spirit: Art, like ethics, is a social product. Ethics are treated in a manner on the whole definitely Spencerian, even to the condemnation of the social-democratic movement. In his discussion of religion, Herr Sack is opposed to Mr. Spencer, and, while owing a good deal to Prof. Max Müller, is original. Not in dreams with their presentment of the dead, not in natural phenomena like sunrise and sunset, not in anything so symbolic as totemism, does the matter of religion arise. They might confirm its sublimity; they are most of them too habitual and ordinary phenomena to create it. It is rather what suggests the invisible, the beyond, the infinite, that originates religious feeling—the horizon, the movement of the wind, the breath of life. Infinite space and infinite movement, and the *anima mundi*, are the elements of the religion of monism, and primitive religion was monistic. Cult degrades it into polytheism, and an interested priestcraft corrupts it; but monism has never been without a witness.

A world of spirits, in the spiritualist's sense, is of course incompatible with such a view. As is individual immortality. In truth, personality other than relative can belong only to the *Allwesen*, "in whom we live, and move and have our being."

In description, Herr Sack often shows a good deal of power. His views in the field of *Religionsforschung* doubtless express something of the truth, though not to the exclusion of other explanations. Indeed, the horizon, and the wind, and breathing are habitual too! Herr Sack's monistic formula, if true, must be established on other lines than his. Its only value here is that of any unverified vaticination that has brought peace to some of our fellow-men.  H. W. B.

*First Stage Hygiene.* By Robert A. Lyster, B.Sc.Lond. Pp. viii + 199. (London: W. B. Clive, 1900.)

In general character this book resembles those already available for students of elementary hygiene and public health. It is intended more particularly for students receiving lessons upon the lines of the syllabus of the Department of Science and Art, now the Board of Education, but it may also be used by other students. The order of treatment differs from that usually adopted, but it may be doubted whether in some cases the change is an improvement. A noteworthy point, however, is that, so far as possible, the physiological facts required to intelligently consider hygienic principles are dealt with as they are required, instead of being described in a separate section devoted to physiology. Another characteristic of the book is that simple experiments illustrating the points described are given at the ends of some of the chapters. There is still room for a book containing not only lecture experiments, but a good course of laboratory work to be done by individual students of hygiene.

## LETTERS TO THE EDITOR.

*[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.]*

### Measurements in Schools. Collateral Heredity.

I am at present engaged on an investigation into the strength of collateral heredity, *i.e.* the degree of resemblance for a variety of mental and physical characters of pairs of brothers, pairs of sisters, and pairs of brothers and sisters. In this matter I cannot seek the aid of parents, for they are scarcely unbiased observers, but I have to appeal for aid to those who teach in schools, and have thus an independent and often extensive knowledge of their pupils' characters. This is very frequently combined with the scientific training and caution which renders the teacher's aid of special value. As it is necessary to obtain measurements and observations of both sexes, I have appealed to both men and women teachers, and as it is also needful to combine the sexes (in the brother-sister measurements) to those working in elementary schools, as well as in boys' public schools and in girls' high schools. The result of my appeal has been to bring me a great deal of most valuable aid. Several high schools have been dealt with, four of our chief public schools have been, or are being measured, and a considerable variety of private, elementary and other schools. But a single public school (even of 500 to 700 boys) will often have only ten to twenty pairs of brethren, not, perhaps, as many as in a village national school, and I am most desirous of getting further help. The determination of the strength of collateral heredity is a problem of great scientific importance, and it can only be achieved by co-operative action. I have found so many teachers in all classes of schools willing to give disinterested aid in the cause of science that I venture to make a further appeal through Nature for more assistance. Besides observations of physical and mental characters, which can be recorded without measurement, my data papers ask for certain head-measurements, which can, following the printed instructions, be taken quite easily. I shall be most glad to send sample papers to any one willing to assist, and if, after considering these, they find themselves able to assist, say by filling in data papers for ten or more pairs of brothers or sisters, I will at once despatch a head-spanner, of which I have several at the present time, free. The head-spanner should not be retained (unless under special circumstances) for more than a few weeks. Where the school is a small one, one master has, as a rule, filled in the papers entirely; in larger schools, one of the science masters, or even the medical officer, has done the head-measurements, and the other data have been provided by house, form or consulting masters. In the ultimate publication of the statistics all aid will be duly acknowledged, but I make the appeal for help simply on the ground that the investigation of heredity is to-day one of the most important scientific problems, and that its exact quantitative determination is well within the reach of co-operative observation.  Karl Pearson.

University College, London.

### The Perseid Meteoric Shower.

In the years from 1893 to 1899 inclusive, about 120 determinations of the Perseid radiant were made. With the exception of three or four positions, the dates of the observations ranged from August 1 to 16, while the majority were for August 10 and 11 only.

It seems of little use to continue accumulating observations of the radiant point on and near the date of its maximum. What we essentially require are observations of the earlier stages of the shower during the last half of July, and as the present year offers a good prospect for obtaining them, I trust observers will make a special effort in this direction. The moon will reach her last quarter on July 19, and will prove a very slight hindrance to observation during the ensuing fortnight. When the sky is clear it should be watched all night, the paths of such meteors as are visible carefully recorded, and the results for each date kept separate, so that the place of the Perseid radiant may be traced in its diurnal motion of about 1° to the E.N.E. Some really good determinations of the radiant in July would be valuable, for very few have ever been made owing to the comparative feebleness of the shower in this month. An observer, however, who extends his watch over a long period, if not over the whole of the night, will find little difficulty in mapping a sufficient number of Perseids to indicate a good radiant.

Bishopston, Bristol, June 10. W. F. DENNING.

### Variations in Plants of the Herb Paris.

THE enclosed table, showing the variations in 200 plants of Herb Paris, picked this month in the woods near Wells, may be of interest to some of your readers, especially if looked at in connection with the memorandum written by Sir Edward Fry, which he is kind enough to allow me to send with it.

L. ELEANOR JEX-BLAKE.

HERB PARIS.

| Plants | Leaves | Sepals | Petals | Stamens | Cells of Ovary | Styles |
|---|---|---|---|---|---|---|
| 96 normal flowers | 4 | 4 | 4 | 8 | 4 | 4 |
| 44 | 5 | 4 | 4 | 8 | 4 | 4 |
| 2 | 6 | 4 | 4 | 8 | 4 | 4 |
| 13 | 5 | 5 | 4 | 9 | 4 | 4 |
| 8 | 5 | 4 | 4 | 9 | 4 | 4 |
| 5 | 4 | 4 | 4 | 9 | 4 | 4 |
| 2 | 4 | 4 | 3 | 8 | 4 | 4 |

| 1 | 5 | 4 | 3 | 8 | 4 | 5 |
| 1 | 5 | 4 | 4 | 8, one double | 4 | 4 |
| 1 | 5 | 4 | 4 | 8 | 3 | 2, and one rudimentary |
| 1 | 6 | 4 | 4 | 9 | 4 | 4 |
| 1 | 6 | 6 | 4 | 8 | 4 | 4 |
| 1 | 6 | 5 | 3 | 8 | 3 | 3 |
| 1 | 6 | 5 | 4 | 9 | 5 | 5 |
| 1 | 6 | 5 | 4 | 9 | 4 | 4 |
| 1 | 6 | 4 | 3 | 9 | 4 | 4 |
| 1 | $5\frac{1}{2}$ | $4\frac{1}{2}$ | 3 | 8 | 4 | 4 |
|  | two halves grew together |  |  |  |  |  |

[Miss Jex-Blake's table seems to me to show many points of interest.

The Herb Paris has long been known to be very variable in the number of its parts; this table quantifies (I use the word, though it used to make a friend of mine very angry) the variability of the plant. It shows that, taking the 96 plants as exhibiting the normal form, more than one-half, *i.e.* 104 out of 200, vary from the standard; that the most variable element is the circle of stem leaves; and that looking at the flowers alone, 142 plants out of 200 are normal, 58 only abnormal; that the 58 thus varying plants fall into no less than 28 groups; that not only do the plants vary as wholes, but that parts usually the same in number, or multiples of the same number, dó not maintain this relation, *e.g.* that in 13 plants you get 5 sepals, 4 petals and 9 stamens, and so on.

The plant being thus given over to variability and belonging to the great group of monocotyledons, in which 3 and multiples of 3 are the dominant number for the parts of the flower, a systematist might expect that the variations of the Herb Paris would oscillate round 3, or a multiple of 3, as the standard form; but, in fact, they oscillate round 4 as the dominant number, the 96 normal plants having that number, or a multiple of that number, everywhere, and 44 plants having that number and multiple everywhere except in the leaves. Nature, therefore, disappoints our reasonable expectation.

It has, I believe, been suggested that the flower of Herb Paris is ideally of 6 and 12 parts, and that it has been reduced to 4 and 8 parts by atrophy and suppression of 2 and 4 parts respectively. If this were a true theory, you would expect to find here and there a reversion to the ancestral form; but the table shows that the number 6 occurs in the floral parts once, and once only, viz. in the sepals, and the number 12 never occurs in the stamens or elsewhere, so that the suggestion of suppressed parts becomes highly improbable.

The Herb Paris wanders from the ordinary type of monocotyledons, not only in the number of the floral parts, but in having ramifying veins of the leaves in the place of parallel veins; there are other monocotyledons which have this variation in the leaf from the standard. Do they, too, show any tendency to vary in the number of the floral parts? or to put it in other words, is there any correlation of the two variations? I have not looked into the subject, but it might prove worth consideration.—E. F.]

May 25.

### Quaternion Methods applied to Dynamics.

I SHALL be obliged if any of your readers can give me the titles of any works on statics, or dynamics, or any physical science which are based on Quarternion methods and use nothing but Quaternion symbols.

The end chapters of P. G. Tait's "Quaternions" give examples; Kelland and Tait work out the theory of strains using Quaternion methods, but neither of these suffice for the purpose I have in view, namely, to put into the hands of a student a text-book on dynamics, &c., written in Quaternion language.

Jubbelpore, June 1. W. G. BARNETT.

---

## *PLANT HYBRIDS.*

HORTICULTURISTS have recognised that as time goes on they must look more and more to hybridisation for "new plants." Biologists are already pointing out that, if anything can, breeding experiments will add to our knowledge of "the species." For both of these reasons the current volume[1] of the Royal Horticultural Society's *Journal* is of very particular interest, seeing that it is in fact the detailed report of the Conference on Hybridisation and Cross-breeding held last summer. The present writer has already summarised in these pages[2] the chief facts of importance brought out in the two days' proceedings; but several of the papers have been elaborated and illustrated, while many further contributions have been sent in and are now published. The latter in particular call for further comment.

Speaking generally of the report, it may be said that it is of very great value as a record of parentage, as a storehouse of many facts, and as putting forth several interesting theories. Furthermore, among the contributors are amateur and professional horticulturists, scientific workers pure and simple, as well as men who combine the interests of both, and this is a decided step in the right direction. It is not to be expected that the collection of papers forms a complete treatise to guide the practical or theoretical student; useful points are only to be found among cases at present not to be reconciled together and along with striking differences of opinion.

The very discrepancies are, however, to be welcomed, for from them can be learned the work to which attention should be most ungrudgingly given in the future; and by the publication of the "Hybrid Conference Report" the Royal Horticultural Society will earn the gratitude of a larger circle than ever. In the present account it will be best to touch upon individual papers rather than to attempt to discuss them together under special headings, as was done before.

---

[1] *Journ. R.H.S.* vol. xxiv. (April 1900), pp. 1–348; 123 Figs.

[2] NATURE, vol. lx. (No. 1552, July 27, 1899), pp. 305–307.

One must not pass over without mention the list of some hundreds of hybrid plants exhibited at Chiswick on the first day of the Conference. In this are given the names of the parent species and of the raisers, as well as notes as to characteristics and habits, and points in which the hybrids most resemble their father or their mother. The generic headings are arranged alphabetically, while several plants and the pitchers of some *Nepenthes* are figured. A page is further devoted to the interesting series of mixed grafts which were also shown. In these the branches of both scion and stock retain their foliage, and in all cases the component plants belong to different genera. The title of "Hybrid Grafts," given to them in the report, does not seem to be a satisfactory one, being open as it is to misinterpretation or to confusion with "graft hybrids."

Dr. Masters' introductory address has already appeared in NATURE (vol. lx. p. 286). Among Mr. Bateson's contentions as to the origin of species, which have not been previously alluded to, is his statement that most professed botanists and zoologists are agreed that no natural species, whether animal or plant, has arisen by direct hybridisation. This may be mentioned, as another contributor to the report expresses the opposite opinion. Furthermore, Mr. Bateson's remarks as to the benefits that many horticulturists might confer upon the student of evolution, by recording even rough statistics, are very much to the point.

*The genus Anthurium.*—M. de la Devansaye says: (1) that in this genus, pollen to be of value must come from plants springing from a different batch of seeds from that giving rise to the ovule-bearing individuals; (2) that pollen from allied genera has a beneficial effect; (3) that variations may not be seen in the first or second generation of hybrids, and yet may appear in the third or fourth. Hence experiments should not be abandoned too soon.

*Monstrosities.*—Prof. Hugo de Vries' paper, read under the title of "Hybridisation as a means of Pangenetic Injection," now appears as "Hybridisation of Monstrosities." There is plenty in it, however, which does not refer to monstrous plants. Variation among hybrids of the first generation, as regards the colour of the flower, in a case considered by the professor, is put down by him as justifying the supposition that they simply inherited their variability from their mother. He lays down as a rule of horticultural practice the choosing of forms to hybridise, of which at least one is known to be very variable. The well-known multiformity of hybrids is stated to arise from this, but the fact—abundantly proved by the Conference—is also noted, that many hybrids can hardly be distinguished exteriorly from one or other of their parents, and therefore may be often mistaken for true species.

*Hybridisation and its Failures.*—Physiological affinity, says Prof. Henslow, it would seem, must be neglected altogether in purely systematic work. He gives many cases where plants that botanically are placed in separate genera or families, on the strength of a single character, will not breed together, and he contends that genera that can be crossed should not be united for this reason alone, for if interbreeding is to be the test, polymorphic forms of the same species would logically have to be separated. The many "failures" recorded by Prof. Henslow must not be all put down as definitely proved to be such, as in many cases adverse conditions, of which the experimenters were ignorant, may have prevailed.

One would be interested to know whether the professor gained much information from the answers to the question set by him at the Royal Horticultural Society's examination last year, which ran, "Give any instances of failures, and state your opinion as to their causes, in crossing distinct species."

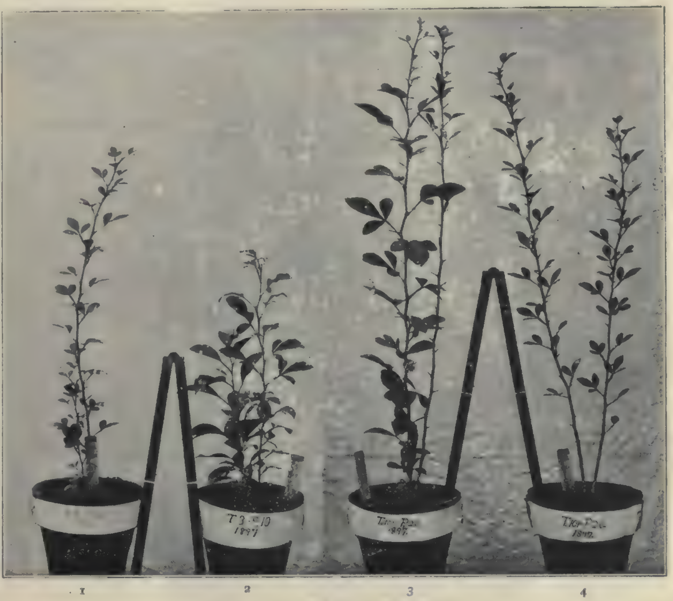

FIG. 1.—True and false hybrids of *Citrus*.

*Official Work of the United States.*—In the previous notice were mentioned the difficulties met with by Mr. Webber and Mr. Swingle, owing to the ovule of *Citrus* producing more than one embryo. In the accompanying illustration (Fig. 1), reproduced from the report by the courtesy of the Royal Horticultural Society, pots 1 and 4 each contain two seedlings of *Citrus trifoliata* type, arising from a single seed, and which show no effects of any cross. In the second pot are three young plants, again rising from a single seed, as determined after it had germinated. The seed was the result of a cross between *C. trifoliata*, ♂, and the Tangerine orange, ♀. One of the seedlings has trifoliate leaves of larger size than the typical *C. trifoliata*, and this is the true hybrid from the egg-cell proper, while the other plantlets with unifoliate leaves, and resembling the Tangerine, are from adventive embryos.

In No. 3, where the parents of the seed were the sweet orange, ♂, and *C. trifoliata*, ♀, two seedlings have grown both with trifoliate leaves, and that having these larger and more abundant may be put down as the hybrid. The other, which is like the mother in every respect, is looked upon as the product of the nucellus. Mr. Webber's other remarks and illustrations apply to the hybridisation of cotton and maize.

*The Structure of Certain Hybrids.*—Dr. Wilson contents himself chiefly with the external structure of hybrid *Passiflora*, *Albuca*, *Ribes* and *Begonia*. His figures bring out very forcibly the intermediate nature of many hybrids. The grades between ideal "tuberous" and "non-tuberous" conditions in hybrid *Begonia* are remarkable, joints of the stem falling away in several instances. We reproduce his illustration (Fig. 2), a flowering shoot of a hybrid between the gooseberry, ♂, and black currant, ♀, and his sections of the ovary walls of the young plant and its two parents (Figs. 3, 4, 5). Several experimenters have obtained the cross and fruit from it, but no seeds. It is interesting that no odour of the black currant is possessed by the leaves, and that the caterpillars of the gooseberry saw-fly attack them without hesitation.

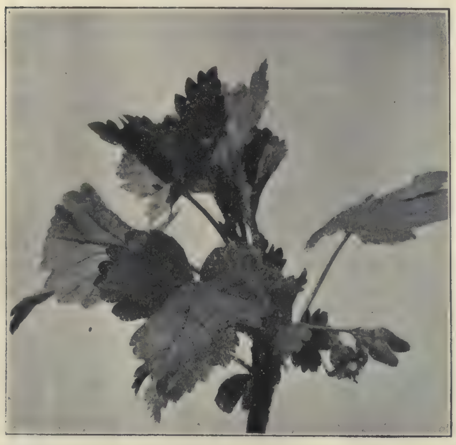

FIG. 2.—Flowering shoot of *Ribes nigrum*, ♀, × *R. grossularia*, ♂, (nat. size).

*Self-sterility.*—It is well that the importance of determining whether a plant may not be self-sterile has been brought out by Dr. F. Ludwig. All the individuals of a species which is propagated vegetatively may, in a particular neighbourhood, be practically the same plant, and incapable of fertilising one another (compare the case of *Crocus sativus* on p. 276). Hence the importance in bringing pollen from physiologically independent individuals at a distance, mentioned in the discussion by the Rev. G. H. Engleheart with regard to daffodils, but not explained by him. Among a series of his opinions summarised conveniently by Dr. Ludwig is one with regard to the springing up of races within the same species, which may be self-sterile and self-fertile. Another is of a very practical nature, and deals with the advisability, when introducing a new species of plant into a garden, to obtain at least two examples of it of as different origin as possible, or to procure the seed of such.

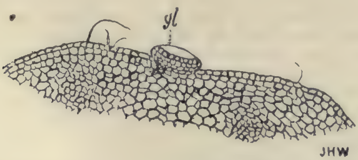

FIG. 3.—Transverse section of part of the ovarian wall of the black currant.

*Work at the Paris Natural History Museum*, 1887–99.—M. L. Henry contributes a list of plants supposed to be hybrids, which he suggests might have their origin proved by hybridisation experiments. He adds a record of his work during recent years, giving most details with regard to lilacs.

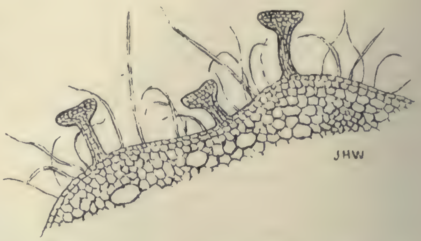

FIG. 4.—Transverse section of part of the ovarian wall of the hybrid.

*Graft Hybrids.*—This account of the Bronvaux medlar, by M. E. Jouin, appeared originally in *Le Jardin* (January 20, 1899); and M. Daniel ("La Variation dans la Greffe," *An. Sci. Nat. Bot.* Series 8, vol. viii. (1898), pp. 1–226; pls. i.–x.) has figured and given some details in his recent paper of the remarkable branches pushed out by the whitethorn stock below the graft.

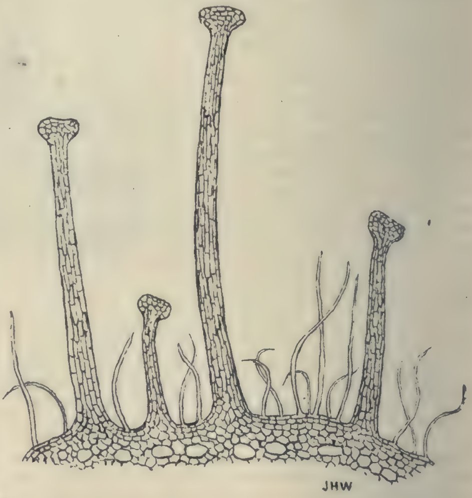

FIG. 5.—Transverse section of part of the ovarian wall of the gooseberry.

Branch No. 1 is intermediate between the whitethorn and medlar. It is, however, thorny, and bears corymbs of as many as twelve flowers, instead of solitary blossoms. The fruits are medlars, but small and much flattened.

Branch No. 2.—The young leaves resemble those of the whitethorn; the older, those of the medlar, being hardly, or not at all, lobed. The flowers are like those of the former plant, and arranged in corymbs, but a trifle larger. The fruits are not medlars.

Branch No. 3.—The base is simply whitethorn, but the extremity is practically like Branch No. 2.

Similar cases are instanced by M. Jouin, who puts down the now celebrated *Cytisus adami* as having arisen in the way that the branches above described have done.

*Drosera Hybrids.*—This paper, by Prof. Macfarlane, has already appeared in the publications of the University of Pennsylvania; it deals with the structure of a batch of natural hybrids. It may be noted that several instances of what the author has called bi-sexual hybridity occur in the plants considered (p. 248); for instance, instead of finding structures intermediate between the elongated glandular hairs of *Drosera filiformis* and the sessile two-celled glands of *D. intermedia*, both appear on the calyx of the hybrid between them. This fact calls forth some interesting speculations of a cytological nature, which the Professor hopes to see verified. As showing the growing opinion in favour of graft hybrids being realities, it might be mentioned that *Cytisus adami* is referred to as such in the paper.

*The Influence of each Parent.*—From experiments with cereals and Bromeliaceæ, Dr. Wittmack concludes that "the mother has the more influence upon the habit; the father the more upon the inflorescence; at least, upon its colour." The contrary opinion of M. Duval is given, who also holds that to reduce the volume of the plant the larger must be fertilised by the small parent species. According to Mr. Tropp, the same holds good usually, but not always, with orchids.

*Principles.*—The laws given by Herr Max Leichtlin may be quoted in full:—

(1) The female parent gives to the offspring the form and shape of the flowers; also certain qualities.

(2) The male parent gives more or less of the colouring of the flowers, and if it be richer and blooms more freely than the female, this property is transferred to the offspring.

(3) Artificially produced offspring give larger flowers than either of their parents.

(4) The more distant the habitats of the species intended to hybridise, the more difficult is it for them to be fertilised with each other's pollen.

(5) The offspring becomes infertile and delicate if the form of the flowers of their parents is widely different in shape and outline.

*Breeding Staple Food Plants.*—In alluding to the cost in labour and money of developing hybrids when the immense number of plants that should be dealt with are used, Prof. Willett Hays points to the importance of selecting carefully the parental individuals. The best flower, he says, too, should be chosen from the best part of the plant.

*An Improved Variety of Crocus Sativus.*—It was not till after many experiments with examples from many places that the saffron could be got to produce seed, except very meagrely (compare the remarks already made on self-sterilising above). After a wild plant of *Crocus graecus* was obtained from the island of Syra, as much seed as was wanted was obtained. In the variety produced by M. Chappellier there is a proliferation of stigmas, sometimes thirty, and even bracts and sheaths have been converted into them.

*Experiments with Dioscorea.*—In an attempt to obtain a tuber which was short enough for one to dig up easily, a plant was obtained by M. Chappellier bearing both male and female flowers. This worker also contributes a note on *Mirabilis*.

*Hybrid Lilacs.*—M. E. Lemoine sends an account of how he proved the Varin lilac to be a hybrid between *Syringa persica laciniata* and *S. vulgaris*, a piece of work which M. Henry would also have succeeded in if his plants had not died before flowering.

*Hybrid Clematis* are dealt with by M. Morel and Mr. Jackman. M. Duval treats of *Anthurium scherzerianum*, of Bromeliads and of Gloxinias. This hybridist points out how important it is to know the pedigree of plants experimented with, and says that the male parent should be most carefully selected, as being the one whose influence greatly preponderates. Mr. Meehan and Mr. Smythe have written a few general notes. Mr. Weekes has a little to say about Chrysanthemums, while Mr. James Lye, when discussing the cross-fertilisation of the *Fuchsia*, states that he uses the tip of a squirrel's tail to transfer the pollen, and prefers muslin bags to those made of paper for enclosing the chosen blossoms.

Mr. Wilks, the secretary of the Royal Horticultural Society, must be complimented upon the successful production of the report. WILFRED MARK WEBB.

## OUR NORTHERN BIRDS.[1]

MR. DIXON is a prolific writer, and confines himself almost entirely to one subject. Nevertheless he always succeeds in interesting his readers, and contrives to say something fresh even upon such a trite and threadbare theme as British birds. In a former volume Mr. Dixon took as his subject "Bird-life in a Southern County"; and in the present work he dwells on the great difference between the bird-fauna of the more northern counties of England and Scotland from that of the south

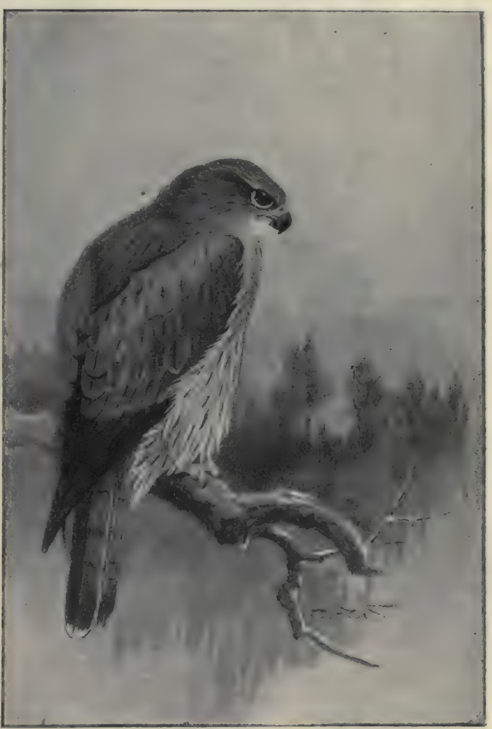

FIG. 1.—Rough-legged Buzzard (From Dixon's "Among the Birds in Northern Shires.")

---

[1] "Among the Birds in Northern Shires." By Charles Dixon. Pp. x + 303. (London and Glasgow: Blackie and Son, 1900.)

of England. Not only are many of the birds of the northern districts normally strangers to the south, either at one season of the year or at all times, but notable differences in their habits are observable. Species, for instance, that sing during winter in the south are silent at that season further north; while others that are permanent residents in the former area are migratory in the latter. And it is certain that from an ornithological point of view the northern counties are more interesting than the southern—and more especially the south-western counties.

In the treatment of his subject, Mr. Dixon has acted wisely in abandoning a systematic classification in favour of a grouping by means of "station," so that we have chapters on the birds of the upland streams, of the moors, the mountains, the heaths and marshes, the forests and copses, the farm and the garden, the river and pool, the sea and the beach, and the crag and sea-cliff. By this arrangement a much more discursive and "chatty" style of writing is permissible than would otherwise have been the case. The reader is accordingly spared a repetition of the descriptions of the various species of which we have already more than enough; and the author has also seen fit to abandon the use of technical names, and to content himself with the English titles of the birds mentioned.

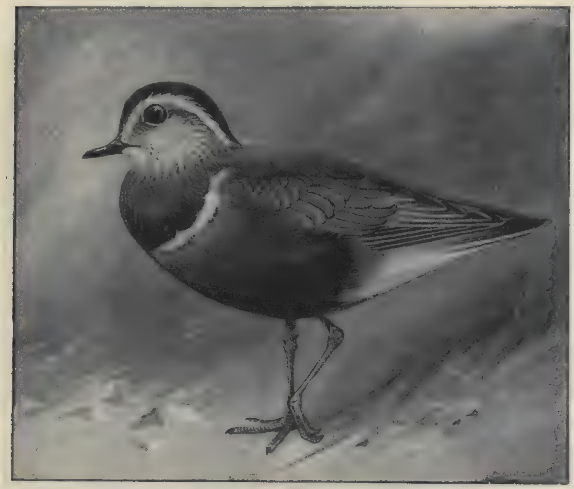

FIG. 2.—The Dotterell. (From Dixon's "Among the Birds in Northern Shires.")

Much of the attraction of the book is due to the exquisite portraits of birds in their haunts from the accomplished pencil of Mr. C. Whymper. Where all are good it is difficult to select examples for special commendation, but the black-cock crowing is one that strikes our own fancy, and the two cuts that we are enabled, by the courtesy of the publishers, to reproduce, will serve as good examples of the general style of illustration. If we mistake not, the figure of the raven is very like one that has appeared elsewhere.

In the chapter on the birds of the upland streams an excellent account is given of the habits of the water-ouzel or dipper; and here the author appears, for once, to have caught Prof. Newton "tripping." In his "Dictionary of Birds" the origin of the name "dipper" is attributed by the Cambridge ornithologist to the writer of the letterpress of Bewick's "British Birds," but Mr. Dixon points out that it occurs in a work published as far back as 1771, and a later issue of which was actually edited by the learned professor himself!

An especial feature of all the author's works is his own practical experience of birds in their native haunts; and all who have had bird-nesting adventures in their own early days will read with delight the description, on p. 136, of his ascent of a lofty oak to secure a clutch of buzzard's eggs, which were safely carried down. In making friends, during his youthful days, with both poachers and gamekeepers, Mr. Dixon seems indeed to have had an almost unique experience, and one whereby his practical acquaintance with the ways of birds was largely augmented. He has many stories to tell of the wanton manner in which he has known keepers fire into the nests of brooding birds and otherwise inflict destruction on what they are pleased to denominate "vermin." In regard to these latter, he urges (p. 151) that our indigenous native game-birds would thrive all the better if hawks, crows, magpies, owls and the like were left unmolested. The pheasant, he thinks, however, might not fare so well; but, he adds in effect, perish the pheasant! This, however, we venture to suggest, is scarcely a practical way of looking at things. If pheasant-preserving were to be given up, our coverts would not be guarded at all, and many of the other birds would be ten times worse off than they are under the present régime.

Not the least interesting chapter in a very interesting book is the final one on bird migration in the northern counties, where, instead of a learned discussion on the theory of migration, we have an actual account of the manner in which the swarms of autumn and spring migrants reach and leave our coasts. Here the author remarks that the short-eared owl and the woodcock frequently reach the Wash together, making the passage from the Continent during the same night, although the one just skims the water while the other flies high in the air. And many other passages attests the author's close observation of the movements of birds. It is to be wished, however, that he would employ the familiar name hedge-sparrow in place of the pedantic hedge-accentor. The term sparrow, as Prof. Newton remarks, was probably originally applied to all our smaller birds; and it is surely an unwarrantable assumption on the part of ornithologists to traverse popular usage and attempt its restriction to the members of the restricted genus *Passer*.

R. L.

## NOTES.

THE delegates to the third biennial conference in connection with the International Catalogue of Scientific Literature were entertained at dinner by the Royal Society as we went to press last week. In the course of the evening several interesting speeches were made in proposing and responding to toasts. Prof. Forsyth, in proposing "International Science," referred to the great empire of science, the possessions and achievements of which are intended for the welfare of all men. Prof. Darboux responded for France, Prof. Klein for Germany, and Prof. Weiss for Austria. The toast of "The Delegates to the Conference" was proposed by Sir John Gorst and responded to by Prof. Ciamician (Italy), Dr. Graf (Switzerland), and Dr. Brunchorst (Norway). Sir Michael Foster proposed the toast of "The Guests," which was responded to by Lord Strathcona; and the health of "The President" was proposed by Dr. Schwalbe and acknowledged by Lord Lister. We have not yet received from the Royal Society the *procès verbal* of the meetings of the delegates, but it is understood that the support promised will warrant a commencement of the Catalogue at the time fixed.

THE third biennial Huxley lecture at the Charing Cross Hospital Medical School will be delivered by Lord Lister on Tuesday, October 2. The two former lecturers, in 1896 and 1898, were Sir Michael Foster and Prof. Virchow.

THE Society of Arts has awarded its Albert medal for the present year to Mr. Henry Wilde, F.R.S., "for the discovery and practical demonstration of the indefinite increase of the magnetic and electric forces from quantities indefinitely small." This principle is the one on which the invention of the dynamo machine is based, and is utilised in the construction of all modern dynamos.

AT the annual general meeting of the Royal Statistical Society, held on Tuesday, Lord Avebury was elected president for the ensuing session. It was announced that the subject of the essays for the Howard medal, which will be awarded in 1901, with 20*l.* as heretofore, is "The History and Statistics of Tropical Diseases, with especial reference to the Bubonic Plague." The essays should be sent in on or before June 19, 1901.

THE annual meeting of the Marine Biological Association will be held at the Royal Society on Wednesday next, June 27.

WE learn with regret that Mr. W. Percy Sladen, for years an honorary secretary of the Linnean Society, died at Florence on June 11.

THE death is announced of M. Boutan, one of the founders of the French Physical Society, and the author of an excellent "Traité de Physique" as well as other works.

PROF. EDMUND PERRIER has been appointed to succeed the late Prof. Milne-Edwards as director of the Paris Natural History Museum.

THE autumn meeting of the Iron and Steel Institute will be held at Paris under the auspices of the Société d'Encouragement pour l'Industrie Nationale, on Tuesday and Wednesday, September 18 and 19.

THE summer meeting of the Institution of Mechanical Engineers will be held in London on June 27 and 28. The programme includes an adjourned discussion on road locomotion (a short supplementary paper dealing with the recent trials will be submitted by Prof. H. S. Hele-Shaw, F.R.S.); recent locomotive practice in France, by M. Edouard Sauvage; polyphase electric traction, by Prof. C. A. Carus-Wilson; observations on an improved glass revealer, for studying condensation in steam-engine cylinders and rendering the effects visible, by Mr. Bryan Donkin.

AN interesting exhibition of objects illustrating the population, monuments, customs, and native industries of the Chawi and Kabyle tribes of Algeria will be on view in the rooms of the Anthropological Institute, 3 Hanover Square, W., until June 23, from 11 a.m. to 5 p.m. The objects were collected in the course of a recent journey in Algeria by Mr. D. MacIver, student of Egyptology at Worcester College, Oxford, and Mr. Anthony Wilkin, of King's College, Cambridge.

THE Advisory Committee appointed by the Board of Trade in connection with the business of the Intelligence Branch of the Commercial, Labour, and Statistical Departments of that office met on Thursday last, Sir Courtenay Boyle being in the chair. There were present, among others, Lord Avebury, Sir Frederick Abel, F.R.S., Prof. Wyndham R. Dunstan, F.R.S., and Mr. C. A. Harris, C.M.G.

THE grant of 1000*l.* in aid of the work of the Marine Biological Association; the site of the National Physical Laboratory at Kew; and the grant to the British School at Athens, were brought before the House of Commons on Friday last, upon the vote to complete the sum of 50,724*l.* for scientific investigation. It was urged by Mr. Gibson Bowles that the grant to the Marine Biological Association should be largely increased; and by Lord Balcarres that the vote of 7000*l.* for building and equipping the National Physical Laboratory should not bind the Treasury to adhere to the site which has been proposed. Mr. Hanbury said it should be borne in mind that the grant of 1000*l.* to the Marine Biological Association was not the only grant made in connection with the fisheries of the United Kingdom. A grant was given to the Fishery Board of Scotland for the purpose of scientific investigation, and similar assistance was given to the Irish fisheries. Under present conditions there did not seem to be any urgent necessity to increase the grant. The Treasury had very little voice in the matter of the Physical Laboratory; it had acted on the recommendation of a committee of the Royal Society. It was absolutely necessary to find a site near Kew Observatory, and after looking at every possible site the committee strongly reported that no other site would answer the purpose so well as that which adjoined Kew Gardens. He agreed that nothing ought to be done which would interfere with the amenities of Kew Gardens, and this point had been considered in the selection of the site. The two buildings, one for the machinery and the other for carrying on the more delicate scientific operations, were to be placed in positions which would not mar the views from the gardens or injure their amenities. The voting of the 7000*l.* would in no way prejudice the consideration of the case against the proposed site.

REFERRING more particularly to the British School at Athens, Mr. Balfour said that the only ground for the alarm expressed was that the original grant was for five years, and that this term was drawing to a close. The question of Governmental subvention of scientific investigation was a very important subject, and there was no doubt that this country had, from a traditional policy, lagged greatly behind other nations in this respect. It never occurred to us to do what the Germans, the French, or the Americans did in making certain grants for investigations; and whether we were right or wrong he did not undertake to say. His own personal inclination was rather in the direction of Governmental aid in cases where they could not expect private aid to come forward; but at the same time he confessed that he often thought how strange it was in a very rich country like ours there were not found some people who, in a difficulty to find other and more profitable investments, did not attempt to earn glory for themselves by carrying on those investigations with the money that was required. He could only say that certainly the grant would not be discontinued without a generous consideration of the facts and interests involved.

A MEETING of the Röntgen Society was held on Thursday, June 7, at St. Bartholomew's Hospital, by the invitation of Dr. Lewis Jones. A large American Holtz machine has recently been presented to the hospital, and it was chiefly to allow the members to have an opportunity of seeing this machine at work in connection with X-ray tubes that Dr. Jones invited the Society to meet at the hospital. Large Holtz machines, though used considerably in America, are rarely seen in this country, where the Wimshurst pattern is more commonly employed. A dark room has been fitted up in the electrical department specially for X-ray work. The wires for bringing the current to the tubes are passed through a partition to the machine, which is on the other side. The observer and the patient are thus in no way disturbed by the movements of the machine, or of the motor or other appliances connected with the working of the same. The light given by the tubes was perfectly steady, which is one of the advantages usually claimed for the influence machine over the coil, although this has been somewhat diminished since the advent of the Wehnelt and Caldwell electrolytic breaks.

MR. J. WIMSHURST, F.R.S., also read a short paper on his work in connection with the design and perfecting of the several forms of his influence machine, describing, among others, the large machine made for and presented to the Science and Art Department, with plates 84 inches in diameter; and another, with twenty-four plates 36 inches in diameter, shown at the Earl's Court Exhibition, and which is now, we believe, in the possession of Dr. J. Macintyre, of Glasgow.—Dr. Rémy, of Paris, showed a new localising apparatus. This consists of a vertical support moving in a socket fixed to the table. The tube is supported by a cross piece at the lower end, under the table, while the fluorescent screen is attached to the upper end, together with two pointers representing the paths of the rays, and held in supports moving in slots or grooves. Two observations are made and the pointers adjusted, after which the apparatus is turned round away from the table, and the pointers lowered until their points meet, thus indicating the depth of the hidden object below the surface. A bullet hidden in a loaf of bread was found in a minute or so by Dr. Rémy.

THE *Scientific American* contains an account of Count von Zeppelin's projected navigable balloon now under construction on Lake Constance. The balloon is to be 416 feet in length and 38 feet in diameter, divided into seventeen compartments, and supported on an aluminium framework. It is to carry two cars and motors, and to be propelled by screws placed in pairs at the side of the balloon and geared to the driving-shaft by two diagonal shafts. In the preliminary experiments for testing the efficiency of the motors, a launch was driven on the lake at from 6·8 to 9·2 miles an hour by aërial propellers. The fuel is benzene, and it is calculated that the balloon will carry sufficient fuel to perform a journey of over 179 miles.

THE cutting of the *sudd* on the Upper Nile and the consequent release of large volumes of stagnant water has, we learn from the *Times*, had an unanticipated influence on the condition of the river at Assuan. From reports received by Sir Benjamin Baker from the engineering staff it would appear that the absence of free oxygen in the water has caused wholesale destruction of the fish. Within a hundred yards of the resident engineer's office at least a million dead fish, ranging in size from minnows to six feet in length, are to be found. This result is consistent with London experience when it was usual to pour crude sewage into the stream. The filtered water, though clear and odourless, was drunk with impunity, but, having no free oxygen, eels plunged into it would struggle violently and finally die of suffocation, as has apparently been the case with the fish in the Nile in the special circumstances resulting from the long-deferred cutting of the *sudd* this year.

SOME notes on New Zealand volcanoes are contributed to the latest volume (1899) of *Transactions* and *Proceedings* of the New Zealand Institute, by Dr. B. Friedländer. A description of an eruption of Te Mari witnessed by him is of interest. The eruption began with an explosion, and masses of ash-bearing steam were ejected. There were at least four different light-phenomena:—(1) the reflection of incandescent matter upon the dark clouds; (2) a large number of red-hot boulders, which were shot high up and fell down in parabolic curves; (3) lightning, due to electricity produced by friction. The lightning appeared in masses of ash-bearing steam; and the ashes were coarse, the single grains being about the size of a pin's head. (4) Blue flames, and probably reddish flames. Some red flames were apparently distinct from the light due to illumination of steam, and the blue flames must have been real. Dr. Friedländer suggests, to account for the flames, that during the explosion there escaped combustible gases which at a certain height above the crater met the oxygen necessary for taking fire. He considers that vaporised sulphur would explain his observations better than hydrogen, the flames of which are less brilliant and less distinctly blue. Another paper of interest to students of vulcanology, in the volume referred to, is a detailed description of the volcanoes of the Pacific, by Mr. Coleman Phillips.

AN official report by Captain R. H. Elliot, upon his researches into the nature and action of snake-venom, is referred to in the *Madras Mail*. Captain Elliott confirms the fact that the mongoose is not immune in the fullest sense of the expression, seeing that it may succumb to a snake-bite, if sufficiently severe, like any other animal. His researches go to show, however, that the mongoose does enjoy a partial and comparative immunity from snake-poison—that is to say, a mongoose takes from ten to twenty-five times as much cobra venom to kill it as a rabbit does, and five to twelve times as much as a dog. M. Calmette gives a somewhat lower estimate than this; but he made only a few experiments, and it is noteworthy that the mongooses that he experimented with were obtained from Guadeloupe, where venomous snakes are unknown. The mongoose was introduced into Guadeloupe (and Barbadoes) some twenty-five years ago with a view to the destruction of rats. Captain Elliott thereupon remarks:—"We are thus led to the interesting conclusion that the introduction of the mongoose into a country in which venomous snakes are unknown has resulted, in so short a period as a quarter of a century, in a very appreciable reduction of the animal's resistance to snake-venom. This fact points strongly to the farther conclusion that the immunity is an acquired one, and inasmuch as the acquired characteristic has been so rapidly and easily diminished, it would appear likely that it must be maintained from generation to generation. Be it remembered that a quarter of a century probably means about fifty generations."

THE growing necessity of obtaining greater speed on railways has of late been freely discussed, and different designs have been put forward favouring very much the idea of a single-rail system resting on supports and its train suspended below. Hitherto all railways of this nature have been propelled by steam or electric motors, but *Fielden's Magazine* (June) describes and illustrates a still later application of this suspended car system, patented by Mr. H. S. Halford under the name of the Halford gradient railway. The remarkable feature about his system is the fact that no locomotive or electric motors are carried, as the train derives its motion by gravitation imparted by raising, as long as this is required, to a slight incline, the section of line upon which the train is running. The track of this railway, which is supported, is divided into sections, the extremities of which can be raised or lowered by hydraulic (or other) power, the operation being performed either automatically by the carriage in its transit or by the driver at will. It is stated that the cars ride smoothly going from one section to another, and also the change of incline is so small and gradual that the lifting of the track is almost unperceived. The Halford gradient railway has yet to see a more practical test, but the following advantages claimed make the devise feasible in many ways:—(1) In all other systems, the greater the load the less the speed; in this, the greater the load the greater the speed. (2) There is no need to stop for coal or water. (3) Its natural tendency must be to increase in speed. A photograph of a working model and diagrams illustrate the article.

CONSIDERING the advances that have been made in the rate of travelling during the present century, it would be unsafe to say that a speed of 120 miles an hour is not attainable The evidence that was produced before a Committee of the House of Commons, in a Bill recently brought forward, was not, however, sufficient to satisfy the Committee that such a rate of speed can be attained with safety to the passengers. The scheme of the inventor, Mr. Behr, was for an electric railway to run between Liverpool and Manchester, and to perform the journey of 35 miles, including stoppages, in 17½ minutes, which would mean a speed of more than double that now attained by the best express trains. The carriages were to be suspended on a single rail resting on A-shaped iron tressels, with two side rails to keep the carriages in place. The idea of carriages being suspended from rails is not new, an electric railway on this principle, 8 miles long, having for some time been in use between Barmen and Elberfeld. The trolley rails there are double, and the speed attained is only 18½ miles an hour. In the Lartigue system, which has also been in use for some years, the carriages are suspended from a single rail, but no high speed is attempted. An experimental railway was constructed at Brussels on the Behr system, when a speed of 80 miles an hour was said to be attained. The sensation produced by the sudden pulling up of an ordinary express train is sufficiently uncomfortable, to say the least, to create considerable doubt as to the safety of stopping a train within any reasonable distance travelling at double this rate. Anyway, the Committee, in the interest of the public, declined to give their sanction to the scheme as presented to them; and while admitting that the mono-rail system when properly matured might make an important development in railway traffic, yet as regards the method of applying the brake-power to trains running at such high speeds, they were not satisfied that the safety of the public was sufficiently provided for.

THE action which the vestry of the Parish of Hammersmith has taken to make known the nature of consumption, and the measures which should be adopted to prevent its spread, is altogether praiseworthy, and other public authorities should emulate it. At the request of the vestry, the medical officer of health, Mr. N. C. Collier, has prepared a report upon the causes and prevention of consumption, and it has been distributed in the form of a leaflet. It is pointed out that "there is now no doubt that consumption is caused by a minute living organism, the bacillus of tubercle, and that the presence in the body of the tubercle bacillus is most rarely inherited, but becomes introduced from without. What is inherited is the non-resistile condition of the vitality of certain cells in the body which are unable to destroy the tubercle bacillus, when it has become accidentally introduced into the system. To prevent consumption it is necessary, firstly, to avoid all those means by which the tubercle bacillus may be introduced into the body; and, secondly, to avoid all those causes which enfeeble the vitality of the cells of the body, and so render them unable to destroy the tubercle bacillus should it become introduced." The hygienic principles to be borne in mind in order to prevent the spread of the disease are briefly summarised, and the information given cannot be too widely known to the public.

THE recent report of progress of the observatory at Colába (Bombay) shows the large amount of work accomplished during the year ending March 1900. In addition to the usual magnetic and meteorological instruments, one of Prof. Milne's horizontal pendulums has been in action for nearly two years. During the year covered by the report, twenty-seven earthquakes were registered, besides 1398 small and local movements. A second horizontal pendulum, designed and made locally, was erected last March. It is similar in principle to the other, but much more sensitive. The record is made mechanically by means of an ordinary crow quill and glycerine ink, writing on paper driven at the rate of five inches an hour, excellent open diagrams being thus obtained.

THE Deutsche Seewarte has recently issued its twenty-second volume of *Aus dem Archiv* for the year 1899, containing valuable discussions relating to the motions of air and sea. Among the most popular subjects we may mention a paper, by Dr. van Bebber, on a scientific basis of weather prediction for several days in advance. The same subject has been treated of by the author, in a preliminary way, in periodical publications, and has already been noticed in our columns. The question is one of great importance, and we therefore refer our readers to the present more elaborate discussion. An examination of the weather conditions of twenty years, as shown by the daily weather charts of the Deutsche Seewarte, has led the author to distinguish five principal types, under one of which the actual conditions may be classed, with a fair degree of probability that the behaviour of the weather (on the Continent) will conform in its general features to that of the type in question. The types all refer to the more persistent areas of high barometric pressure, in contradistinction to the more mobile areas of lower barometric pressure. The paper is accompanied by sixteen charts and diagrams printed in the text, and will repay careful study by those interested in weather prediction.

WE have received a double number of the *Journal* of the Scottish Meteorological Society, completing vol. xi. (3rd Series) of this useful publication. It contains the usual valuable meteorological returns from the Scottish lighthouses, and from a large number of stations belonging to the Society. These observations (which refer to the years 1897 and 1898) have been carefully examined; and monthly means have been calculated and utilised in the preparation of the annual reports on the meteorology of Scotland. In addition to this routine work, the number contains several special discussions, *e.g.* the "Annual Rainfall of Scotland from 1800 to 1898." This is a comprehensive and laborious compilation, by Dr. Buchan, and will be of the greatest utility in any inquiry bearing upon the rainfall of this part of the United Kingdom. The tables are divided into two parts, showing (1) the annual amounts, and (2) the average rainfall for the whole period, the heaviest and least yearly amount, the height of the station, and other particulars. Among the other papers may be mentioned "Barometric and Thermometric Gradients, 1704–1898," showing the differences in the mean monthly and annual values of these elements at London and Edinburgh, by Mr. R. C. Mossman. We are glad to see that the important work of the Ben Nevis Observatories will be completed in the way desired by the directors, thanks to the magnificent donations of two of the members of the Society.

THE Wisconsin Geological Survey sends us the third number of an "Economic Series," a "Preliminary Report on the Copper-bearing Rocks of Douglas County, Wisconsin," by Dr. Ulysses S. Grant. The copper occurs mainly as the native metal, and most commonly in the upper amygdaloidal parts of the old lavas belonging to the Lower Keweenawan (pre-Cambrian) formation. It occurs also in small particles scattered through both igneous and stratified rocks, in minute seams and in veins. It was deposited in its present position by circulating waters. At times, at the surface the native copper is not discernible, and its presence may then be detected by the green and blue alteration products or stains, malachite or azurite. Areas where the rock is highly charged with epidote are of a yellow or yellowish-green colour, and it is recommended that these be searched for particularly, as in them copper is likely to occur. The rocks of Douglas county are the same in nature, in origin and in age, as the copper-bearing rocks of Keweenaw Point, Lake Superior; but at present it has not been determined in Douglas county that any deposit of copper of sufficient richness is extensive enough to be of economic value. Some of the recent explorations are, however, very encouraging.

THE *Quarterly Journal* of the Geological Society for May is a bulky number, which contains the address of the ex-president, Mr. Whitaker, and fourteen papers dealing with a variety of subjects. Perhaps the most important of these are contributed by women, who, by the by, are not at present eligible to become Fellows of the Society. There can be no doubt, however, that the essay by Miss Gertrude Elles on the zonal classification of the Wenlock shales of the Welsh borderland, and that by Miss Ethel Wood on the Lower Ludlow formation and its graptolite-fauna, make very great advances on our previous knowledge. The papers bear evidence of long-continued and critical research on the Silurian strata and on the difficult subject of the zoological characters of the graptolites which characterise successive stages in the rocks.

THE volume of "Geological Literature," which since 1895 has been separately published by the Geological Society of London, reflects great credit on the compiler, Mr. W. Rupert Jones, and on the editor, Mr. Belinfante. In this work the titles are given of the books and of all the geological papers contained in periodicals which have been added to the Society's library during the year 1899. This list occupies over a hundred pages, while the subject-index brings the total to 176 pages. As a work of reference it is indispensable to all geologists.

THERE is now in the press, and will shortly be published by Messrs. Young, Liverpool, and Messrs. Porter, London, the report of the conjoint expedition to Sokotra and Abd el-Kuri, conducted in 1898–99 by the British Museum (represented by Mr. Ogilvie-Grant, of the Zoological Department) and the Liverpool Museums (represented by the director of museums to the Corporation, Dr. H. O. Forbes). The expense of its publication is borne by the Museums Committee of the Liverpool City Council, and the volume is edited by Dr. Forbes. It will be illustrated by between twenty-five and thirty plates, chiefly coloured, depicting the zoological and botanical discoveries of the expedition, the ethnography of the islands, &c. The introductory chapters by the editor give an account, fully illustrated by blocks, of the journey, of the geography of the islands and of their inhabitants. The scientific chapters are contributed by Lord Walsingham, F.R.S., Prof. I. B. Balfour, F.R.S., Mr. Boulenger, F.R.S., Dr. Forbes, Mr. Ogilvie-Grant, Mr. A. E. Smith, Colonel Godwin-Austen, F.R.S., Mr. De Winton, and other well-known naturalists.

THE last number of the *Zeitschrift für wissenschaftliche Zoologie* contains an elaborate paper, by Dr. E. Zander, on the male reproductive organs of the Hymenoptera. It is illustrated by a remarkably well-executed coloured plate.

A CORRESPONDENT of *Nature Notes* asks for some good reason why a lover of animals should not wear the stuffed head of a bird or other creature as an ornament. The query appears to us a pertinent one.

WE have received the Report of the South African Museum for 1899, in which the Trustees express themselves generally well satisfied with the progress of the institution. They record an addition to the edifice of a large block of new building to receive the art collections.

IN No. 3 of *Marine Investigations in S. Africa*, Mr. G. A. Boulenger describes an example of the rare unicorn-fish (*Lophotes cepedianus*) from the Cape of Good Hope, where it has not hitherto been definitely known to exist. The specimen was considerably over a yard in length. The unicorn-fish, which is an ally of the ribbon-fishes, takes its name from the peculiar filamentous process arising from the front of the elevated head.

THE Annual Report of the Field Columbian Museum, containing an excellent portrait of its founder, Marshall Field, is likewise to hand. The museum appears to be making extremely rapid progress, its ethnological series having been very largely increased by the acquisition of the rich collection acquired by the Stanley McCormick Expedition among the Hopi Indians. An especial feature of the report is the introduction of a number of photographs of recent acquisitions. Among these, we may call attention to the portrait of a Hopi bride, and also to a plate of a group of the extraordinary gigantic spiral fossils known as "devil's corkscrew," or *Daemonelix*, which have lately excited so much interest.

THE Imperial Department of Agriculture for the West Indies has just issued a small pamphlet on the best means of destroying that troublesome insect, the "moth-borer" (*Diatraea saccharalis*), which inflicts so much damage, while in the caterpillar stage, on sugar-cane. It appears that a considerable number of the eggs of the moth-borer (which are laid in patches on the leaves of the sugar-cane) are attacked by parasites which prevent the development of the caterpillars, and in due course come forth as flies. These parasite-infested eggs are readily distinguished from healthy eggs by being black, instead of yellow or orange. It is recommended to destroy all the yellow and orange eggs that can be collected, but to leave the black ones, in order that they may breed flies to destroy other clutches of eggs. If this remedy were adopted as soon as the young cane commences to show, and continued as long as it is sufficiently small, the loss of the best shoots would be avoided. If, however, the caterpillars are allowed to hatch out and bury themselves in the cane, there is nothing for it but to cut out the "dead hearts," and this to a considerable depth. When cut out, they must forthwith be destroyed, or the caterpillar will either complete its development in them, or crawl out to other canes.

*Bulletin* No. 2 of the West of Scotland Agricultural College is a report by Prof. R. Patrick Wright on experiments on the manuring of rye-grass and clover-hay in 1899.

THE following are the most recent official botanical publications which have reached us from the United States:—The germination of seeds as affected by certain chemical fertilisers, by Mr. G. H. Hicks (U.S. Department of Agriculture, Division of Botany, *Bulletin* No. 24); Bread, and the principles of bread-making, by Helen W. Atwater (U.S. Department of Agriculture, *Farmer's Bulletin*, No. 112); Co-operative experiments with grasses and forage-plants, by Dr. P. Beveridge Kennedy (U.S. Department of Agriculture, Division of Agrostology, *Bulletin* No. 22).

UNDER the title of "Annuaire des Mathématiciens," Messrs. Georges Carré and C. Naud propose to publish a directory containing the names, addresses and academic rank of those interested in the study of mathematics.

MUCH information is given in a clear and concise form in Mr. A. A. C. Swinton's little book on "The Elementary Principles of Electric Lighting" (Crosby Lockwood), the fourth edition of which has just been published. The book only runs into sixty-four pages, but everything in it is to the point; and electrical artisans, as well as readers unfamiliar with electrical phenomena and effects, will find its pages perfectly intelligible.

**THE** first part of Dr. Carl Chun's narrative of the cruise of the *Valdivia* and the scientific work accomplished, which has been published by the firm of Gustav Fischer, Jena, shows that the complete work, "Aus den Tiefen des Weltmeeres," will be a most interesting account of a successful expedition. The descriptive matter is untechnical in style, and liberally illustrated with excellent half-tone blocks and plates reproduced from photographs. The complete work will contain six chromolithographs, eight heliogravures, thirty-two full-page plates, and about 180 illustrations in the text. There will be twelve parts in all, two of which will be published every month, and the whole by November next. The work will be a *Challenger* narrative on a small scale, full of interest to all students of natural history and of physical geography in the most comprehensive sense of the term. We propose to review it in detail when all the parts have been received.

PROF. E. B. WILSON's work on "The Cell in Development and Inheritance" (The Macmillan Company) contains a masterly treatment of the facts of cell-structure and division, and is favourably known to many biologists. It originally appeared in 1896, and has already been reviewed in NATURE (vol. lv. p. 530). Since then the aspect of many important questions with which it deals has been greatly changed, more particularly in case of those focused in the centrosome, and involving the phenomena of cell-division and fertilisation. This has necessitated a complete revision of the work, and there is scarcely a page of the second edition, which has just been published, that has not undergone alteration. More than a hundred pages of new matter have also been added. The most important results of modern cell-research, especially on the zoological side, are brought together in the volume, which will continue to be used as a convenient and clear synopsis of a vast amount of knowledge to which additions are constantly being made.

**THE** additions to the Zoological Society's Gardens during the past week include a Grivet Monkey (*Cercopithecus griseo-viridis*) from North-east Africa, presented by Mr. H. G. F. Stallard; a Campbell's Monkey (*Cercopithecus campbelli*) from West Africa, presented by Miss E. B. Hall; two Palm Squirrels (*Sciurus palmarum*) from India, presented by Mr. W. B. Bingham; two Common Squirrels (*Sciurus vulgaris*), British, presented respectively by Dr. J. L. Williams and Mr. G. S. Johnson; an Egyptian Jerboa (*Dipus aegyptius*) from North Africa, presented by Lady Preston; an Angola Seed-eater (*Serinus angolensis*) from Angola, presented by Miss Long; a Yellow-billed Sheathbill (*Chionis alba*), captured at sea, presented by Captain Bate; ten African Walking Fish (*Periophthalmus koelreuteri*) from West Africa, presented by Dr. H. O. Forbes; a Hocheur Monkey (*Cercopithecus nictitans*), a Moustache Monkey (*Cercopithecus cephus*), a Malbrouck Monkey (*Cercopithecus cynosurus*), an Angolan Vulture (*Gypohierax angolensis*) from West Africa, a Chacma Baboon (*Cynocephalus porcarius*, ♂) from South Africa, a Negro Tamarin (*Midas ursulus*) from Guiana, two Wandering Tree Ducks (*Dendrocygna arcuata*) from the East Indies, four Anderson's Tree Frogs (*Hyla andersoni*), four Changeable Tree Frogs (*Hyla versicolor*) from North America, deposited; an Orinoco Goose (*Chenalopex jubatus*), a Blue-fronted Amazon (*Chrysotis aestiva*, var.) from South America, a Little Guan (*Ortalida motmot*) from Guiana, a De Filippi's Meadow Starling (*Sturnella defilippi*) from Argentina, purchased; two Collared Fruit Bats (*Cynonycteris collaris*) from South Africa, received in exchange; three White Ibises (*Eudocimus albus*), six Glossy Ibises (*Plegadis falcinellus*), bred in the Gardens.

## *OUR ASTRONOMICAL COLUMN.*

FRENCH OBSERVATIONS OF THE TOTAL ECLIPSE OF THE SUN.—The *Comptes rendus* of the Paris Academy of Sciences for June 5 (vol. cxxx. pp. 1495–1529) contains the preliminary reports of several of the French astronomers who made observations of the recent total eclipse.

M. le Compte de la Baume-Pluvinel, observing at Elche, near the east coast of Spain, successfully carried out a very extensive programme. Nine photographs of the corona were obtained with objectives of 1·50 metres focal length; on these he says the coronal structure is almost identical with that he observed in 1889 at Salut. The planet Mercury is shown on all these plates, and will be useful for their accurate orientation. Three plates were obtained with a lens of 2·70 metres focal length, in conjunction with a cœlostat. For spectroscopic work three instruments were employed. A single prism spectrograph, with the slit in the line of the solar equator, showed the continuous spectrum of the corona extending to 12′ from the limb. Thirty-five bright lines were recorded, more intense on one side than the other. A second spectrograph had two objective prisms of spar and quartz; plates taken with this showed numerous chromospheric arcs, and a strong one due to the corona, this latter having no definite outer boundary. One interesting plate taken some seconds after totality still shows chromospheric arcs, and will furnish measures of the thickness of the chromospheric layers from the actual limb of the sun. An attempt to observe with a powerful six-prism spectroscope for special examination of the principal coronal radiation was rendered difficult by the feeble intensity of the image.

M. Ch. Trépied, director of the Algiers Observatory, also communicates a number of successful results. In addition to many accurate visual observations, twenty-eight photographs of the partial phases were made; six of the corona during totality, using an objective of 0·16 metre aperture and 1·03 metre focal length; the coronal extensions are recorded to 3·5 lunar diameters from the limb. Spectroscopic photographs were obtained with a Thollon prism spectrograph, an attempt being made to record the spectrum of the corona at diametrically opposite regions.

M. G. Meslin and party at Elche obtained eight photographs of the corona with a Henry lens of 16cm. aperture and 1 metre focus, and wide angle photographs of the region round the eclipsed sun for recording new objects. A photograph of the spectrum of the corona was obtained with a concave Rowland grating of 3 metres radius of curvature, used with a heliostat. The second order was photographed on plates 13 × 18cm., the spectrum extending from F to M; the images of the chromospheric radiations being portions of circles 16mm. in diameter.

THE TOTAL ECLIPSE OBSERVED AT SEA.—In an interesting letter written to the *Gibraltar Chronicle* of May 30, Colonel E. E. Markwick describes the appearance of the recent total eclipse as he and other fortunate passengers observed it from the Orient Steamship Company's R.M.S. *Austral.* The Company had considerately arranged that the vessel should be so navigated as to be near the central line of totality at the time of the eclipse, and, thanks to the skill of those in charge, this was accomplished with perfect success.

The position of the ship during totality was about Long. W., 9° 27′, Lat. N., 41° 3′, this being about 50 miles west of Oporto; the duration of the eclipse was about 1m. 31s. The Orient Company had provided an ample supply of glass plates, which, when smoked, permitted the passengers to view the progress of the partial phases, opera glasses being substituted during totality. During the eclipse the sky near the horizon was a lurid yellow, the clouds visible being reddish; the sea looked dark and sombre against the bright yellow of the sky. Close to the sun, however, the sky was quite blue; the darkness during totality was just sufficient to interfere with distinct vision.

The success of this enterprising project will probably induce many would-be observers in the future to adopt this exceedingly convenient and comfortable style of eclipse expedition; the departure from regular routine, though slight in itself, furnishing opportunity for really important scientific operations without disorganising any of the usual arrangements of the observers.

NEW VARIABLE STAR IN CEPHEUS.—Prof. W. Ceraski, of Moscow, announces in the *Astronomische Nachrichten* (No. 3644) that Mdme. Ceraski has found a new variable on examination of plates taken by M. Blajko. The star is not in the D.M., and has the following position :—

$$\left.\begin{array}{l}\text{R.A.} \quad 0\text{h. } 28\text{m.}\\ \text{Decl. } +79^\circ\ 33'\end{array}\right\}1855.$$

The brightness varies from between 8–9 to about 12 magnitude. It was increasing in October 1896, and decreasing in October 1897; it was almost at minimum during May 1898, April 1899, and at commencement of May 1900.

EPHEMERIS OF EROS.—Herr F. Ristenpart communicates a revised ephemeris of this planet to the *Astronomische Nachrichten* (Bd. 152, No. 3643), as follows :—

*Ephemeris for 12h. Berlin Mean Time.*

| 1900. | | R.A. | | | | Decl. | |
|---|---|---|---|---|---|---|---|

HOWE'S PHOTOGRAPHIC OBSERVATION OF EROS.—Mr. A. C. D. Crommelin writes to point out an error in our note on the above, in which it was incorrectly stated that Prof. Howe's photographic observation of Eros was obtained during the solar eclipse of May 28. The photograph was taken before sunrise on the morning of the eclipse, some hours before totality. The error was introduced by the report of the observation being included in reports of the eclipse, and if uncorrected might lead to wrong estimates of the comparative brightness of the planet and of the darkness of the sky during totality.

---

## A MODERN UNIVERSITY.

### I.

THE granting of a Charter to the University of Birmingham, which has just become an accomplished fact, forms a fitting climax to an educational movement which may turn out to be one of the most momentous of the century. We have seen University Colleges called into existence in the great cities of the land by the perception of leading citizens that culture and scientific education of a high type must be brought to their doors and made accessible to all; and we have seen the chairs of those colleges occupied by men who have devoted their spare time to the advancement of learning in various ways. All this has been of the greatest interest in the past and is full of hope for the future.

Side by side with these colleges there is now growing up in many cities a Technical School generally under Municipal Government, wherein artisans and hand workers generally may be trained in their craft, and in the main principles underlying it, in a more direct and satisfactory manner than by the old system of apprenticeship.

Such schools can no more turn out a finished artisan than the colleges can turn out a finished scholar. Much remains to be learned in later life and in the actual pursuit of trade or profession, but the early stages are overcome not only more rapidly, but far more thoroughly, by aid of direct instruction; and in the more favourable cases a substratum of scientific knowledge is laid, and a grasp of principle attained, which must be of the utmost benefit hereafter, and could never have been obtained on the old plan. It is this scientific training in principles which is the really needful thing, when the public is educated enough to perceive it; it is this which is of interest to the educationist, and not a mere instruction in handicraft: it is the making of men, and not the making of machines, which is of vital importance to the future of a country.

Without a training in principles a man remains ignorant and narrow, limited to the performance of the one thing which he has been trained to do, and incapable of turning his attention profitably to anything else; inelastic and incapable of devising or of assimilating modifications and developments, which, as they come in, tend to leave him stranded and belated, waiting only for a period of slacker demand to throw him out of employment. And even if the artisan and the foreman are well educated, there remains his employer to be considered. If he is ignorant—too ignorant to turn his enterprise in the right direction when opportunity offers—his workers must suffer, and the whole nation suffers with them. But though Colleges and Technical Schools impart education on the one hand and instruction on the other; though they enlarge and make more real the education available to the average citizen, they do not control and modify the educational ideal of the country. That ideal remains in many respects still essentially the same as it was at the beginning of the present century, before all this amazing inrush of new knowledge. The new knowledge has not yet been incorporated into education. The half-hearted effort made by schools to introduce what they term a "modern side" only serves to emphasise the blankness of the prospect. They say, and say truly, no doubt, that the new studies do not answer. They do not pay either for Government appointments or for the university. But a new university, able to set its own standards, select its own faculties, and set its seal on students of its own subjects, has far larger possibilities before it. It can control, and not only impart, edution. It may need an effort to rise to its privileges. The easiest plan is to follow the lead of others and establish degrees on the worn old lines, but that is not what we expect and hope from the new university of the Midlands. We hope to see it break away from mediæval traditions and realise the need there is for a new educational ideal.

The aim we have before us is an aim at actualities rather than at artificialities; at real things rather than at conventions.

There is a stage of thoroughness at which a study of the conventionalities of grammar and orthography is able to convey real information about men and things—the advanced stage when it becomes the science of philology—but as usually learnt by ordinary persons it is little better than a conventional code and set of rules. If there was little in the world to learn about—as in the middle ages there was but little—it might be well to spend much time in acquiring precisely the gender of nouns and the terminations of irregular verbs in different foreign tongues; not only for practical purposes but for mental training; but amid the superfluity of real subjects of the present day, of all of which the ordinary person is densely ignorant, to immerse him for a long period in these barren studies is wasteful of his youth.

On the other hand, History is reality; and some knowledge of history is necessary for every one. Art, again, and Literature and Music are, or may be, realities; and the vast majority who have no power of creation should at least learn reverently to appreciate the great work of the greatest masters in all subjects, unless they are deaf and dumb and blind. The things really valuable to the human race should be made in some degree accessible to all, and this part of the work of education the Press and the Stage indirectly in some degree accomplish; imperfectly, no doubt, but often more really than do the bodies which make the attempt in a more academic way.

Thus we would discriminate between the conventionalities of language and the realities of literature, just as we discriminate between the laws of colour and perspective, the technique of the painter on the one hand—and the great work of art itself, the expression of a thought or of an emotion, or of a beauty or of a fact. To the scholar, as to the painter, the two are inextricably interwoven; technique is the material in which he works; but the general human race, who have to do the work of the world, and who constitute the bulk of the nation, are neither scholarly nor artistic, and it is both wasteful and cruel to plunge them into technique, and disgust them with the—to them—dull and meaningless details, instead of educating them in the finished work possible only to masters of the craft.

The same sort of things do we say of science and of mathematics. Here, again, there is too great a tendency to educate youths in subtleties and artifices and minutiæ, as if they were going all to be accomplished mathematicians or men of science. The teacher is himself, perhaps, a mathematician, and so thinks that what was necessary for him is suitable for everybody. More usually, of course, the teacher knows very little about it, and feels only that he was himself taught that way, and that he must pass it on. Only a few stop to think what they are doing, and these are the educationists; what they have to say is written at large, and there is no need to repeat it. Some of them are faddists, doubtless; not all are wise; but it is well at any rate to try and think a matter out; and the speculative teaching even of a faddist is likely to be more stimulating than the tenth-hand droning of a conventional pedagogue. To indicate our meaning in terms of mathematics and science, as we have tried briefly to indicate it in the domain of more humanistic studies, we would say that a good deal of the teaching of Euclid and algebra and trigonometry is conventional, and unsuitable to the average youth. If a youth is going to be a mathematician, it matters very little how he is taught these things, so long as they are put in his way. He can hardly have too much of them, he can look at them every way and they present no difficulty; but even the young mathematician might be saved the wearisome and long continued grind through the conventional books of Euclid, with the result that at the end he knows about as much geometry as a month of reasonable teaching would have given him. It is not mathematics at all that he is studying when he is doing Euclid in the usual way, it is a piece of old world literature, very admirable in its proper place, no doubt, and read through at a fair pace quite interesting. It is at any rate far more interesting than the military despatches with which so large another portion of his time is usually, at the same time, being burdened—a form of literature which is not of the slightest interest, and leaves no residue of real information in his mind, except that Gaul used to be divided into three parts; that Cæsar's army built an ingenious and highly technical bridge; that he had difficult times in conquering a people who are not our ancestors, but who happened to occupy the same plot of ground on the earth's surface as we do now.

The conventional part of algebra we refer to may be illustrated by G.C.M. and other rules which in actual work are never needed or employed even by mathematicians. Factors and Equations and Progressions are well enough,—all those parts that are really used or likely to be used hereafter, and all those parts which give a firmer grasp of principles.

Thus in arithmetic, familiarity with such a subject as scales of notation—with the principles, that is, of Arabian numeration—will be really educative and far more helpful than excessive repetition of a rule called "practice," and much dealing with commercial articles. A variety of problems from mensuration, mechanics and heat might be introduced into arithmetic, and the subject made more living than it is apt to be. Mensuration and practical trigonometry may be made truly educative subjects, and a quantity of arithmetical exercises may be founded upon things actually done in the workshop, the laboratory and the field, in the working out of which boys might readily be got to take a real interest.

But all these are school subjects. What have they to do with a university? They have a great deal to do with it in reality, for it is one of the functions and the privileges of a university indirectly to control, or rather influence, the schools. The influence is quite natural and unavoidable anyhow, but on the side of exhibitions and scholarships it becomes obvious and direct.

The schools must train largely for the universities, and the universities must train largely for life.

Now it is just in this training for life that the universities have proved deficient. The only life they have contemplated has been that of the politician and the lawyer on the one hand, and the scholar and recluse on the other. The kind of training needed or supposed to be needed by the past generation of statesmen has been supplied—with results not wholly and completely satisfactory; the kind of training needed for the highly specialised scholar has likewise and will always be supplied. The ancient universities are the natural homes of this kind of learning, and no modern institutions can hope or should attempt to compete with them. The aroma of centuries is a unique growth, and should be carefully fostered and reverenced by a busy and pushing generation.

It would be a calamity if anything were done to destroy the peace and old world quiet of mediæval institutions, founded on monastic traditions and full of attraction for the few who are called to be learned. That Oxford should specialise in archæology and ancient philosophy is most appropriate; that it should regard with jealous eyes the learning of the present century, and hesitate about letting its old bottles be endangered by the inclusion of new wine, is natural and may be wise. We would urge its custodians jealously to preserve the old learning, and leave experiments in new developments to younger and less fragile growths. We would treat the old universities like old buildings, relics of the past, to be most carefully preserved, and supplying something in the life of the nation which no amount of energy or reforming spirit is competent to supply.

If this old world atmosphere disappears it is an irreparable loss. Let its custodians be jealous and conservative; if they see no way of engrafting the new learning on the old stock, without ruining it, then it were far better that the new learning should be planted in fresh soil.

Such soil is furnished by natural circumstance at the intersection of great trade routes, at the market places of the world. Here the average man is at his strongest and busiest, here he is most actively in touch with life on this planet, and is serving his day and generation with an energy which is unmistakable. The motives, doubtless, are mixed, and the results are mixed, there is little Utopian about them; yet there is real self-sacrifice for a far-off good instinctively felt. Ugly surroundings are put up with, as a concomitant apparently necessary, and as at any rate temporarily unavoidable; and life is lived hard for an end not often clearly grasped, yet powerfully felt to the uttermost parts of the Empire. It is on such strenuous home industry, of director, of manager, of foreman, of artisan and of salesmen that our empire is established; and if there is one thing that we are more powerfully realising at present than another it is that our empire must be consolidated, that fresh guiding force must be available, not mere energy—of that there is plenty—but more directing force, more intelligent guidance, more discrimination, more breadth of view—in a word, more real education.

The present war will wake the people of these islands out of their comfortable lethargy. They will see that to hold our position in the modern world we require improved training, not only in rifle shooting and artillery practice, but in every department of activity. Other nations are leaping to the front and spending public money lavishly to get their people better educated, better fitted for seizing new ideas and applying them; it will never do for us to lag behind.

A few scholars, a few men of science, a few men of genius in various branches, these will not save a nation. They extend its fame, they adorn it, they stimulate it, and they reward it; but the backbone of a nation is the average man, the average man of affairs, the man who does the business of the world. If he breaks down or is crippled, the ornamental head cannot be supported. He may be a professional man or a merchant, or he may be a manufacturer or a tradesman, but whatever he is, he must not rest on his oars and be content with the tradition of the past. We are entering a new century, many traditions of the past are out of date, and the vital thing for the nation to realise, if it is to maintain its hard won supremacy, is that antique methods of education will no longer serve. They have had their day; they need not yet cease to be, but they must be supplemented by others. The modern university must take care of the average man. Plenty of long-established universities will look after the high honours men, and in every department highly specialised training is already available; our artisans are as skilled, each in his narrow groove, as it is possible for man to be—marvels of mechanical skill they are; but where is the breadth of view, the elasticity, the power to modify, to invent, to reform, to seize new conditions, to adapt one's self to the growing and changing needs of the world? A foreign order comes to an engineering works of the present day with its sizes expressed in decimals. Before the order can be given out it has to be interpreted into the clumsy sixteenths and thirty-seconds and sixty-fourths of an inch, which alone the workman understands.

Nor is this portentous ignorance limited to workmen. Directly the domain of science is touched, your ordinary school-trained average man is stranded—he is ignorant even of the scientific alphabet—scientific principles are a sealed book to him: the divorce between science and practice, except in the case of a few leading firms who have already wakened up like their continental confrères, appears to be complete.

The modern university must aim for a long time not at depth so much as at breadth. Depth for the few, breadth for the many. It must seek to turn out all-round men, and not specialists only.

Its graduates should not one of them be illiterate, not one of them ignorant of the fundamental principles of science. Trained scientific men they cannot be, in any numbers—the idea would be absurd—but they should have sufficient education to understand a scientific question and know where to go for the answer. They should have lived for a time—even a short time—in the atmosphere of science, and thereafter it will never be quite strange to them.

The scientific training need not be given solely in an academic manner, aloof from all questions of practical interest.

Some people are best trained in this manner, but other persons with a vivid practical interest or experience in application to life and work are best trained in close touch with practical conditions. Medical training is the best example; that is thoroughly done. We would have other training arranged on the same practical lines. The modern university will seek, so far as it can, to allow for differences of aptitude, or, it may be, differences of preliminary training. It will not seek to force every undergraduate at first through an arts course, and then through a science course, and then through a technical course. It may be well to do this with professional men, but not with all. Every graduate should pass through these three stages before he can be turned out a useful and educated citizen, fit intellectually to take his share in the work of the world; but he need not in every case of necessity take them in this logical order.

To force a boy through a course of language or history or literature, at a period when for some reason he is not attracted by it, is doing him but little good. It may, indeed, do him harm, by breeding disgust for subjects which at a later stage he might realise were necessary, and, when properly taught, enthralling. It is love of culture, and not hatred of it, that should be implanted. The so-called "preliminary in arts" course should be taken compulsorily at some stage of a graduate's complete career, but not necessarily at the beginning. A student who has been immersed for a term in purely technical studies will, if he is good for anything, turn to such human subjects with relief; and it is not fair to turn him out in the world without some worthy human interest and solace. The university has failed in one of its functions if it permits him to depart trained in nothing but unhuman technology.

But then, on the other hand, the arts man, the lawyer, the merchant, the man of business, and still more the teacher—how much better would they not be for a tinge of scientific training. Their ignorance does not come home to all of them, but to many it does; and probably in middle life they strive, by attending popular lectures and miscellaneous semi-scientific entertainments, to obtain a growth by a top-dressing of superficial information never really assimilated, seldom adequately understood. A manuring of science placed low down when young would have rendered the surface soil fertile, and this later growth easy, just as the youthful smattering of letters renders moderately easy and interesting the subsequent reading of history, or, in some cases, even the learning of a new language; but to the wholly untrained person these things are, and remain, hopelessly difficult.

A broad training all round can only result in what specialists would call a smattering—what we should prefer to call a leaven; but so long as it is not confined to a learning of trivial details, but represents a grasp of some of the fundamental principles of a subject, it is all that most men ever have, or can have, in any branch but their own, however highly educated they may be. It takes a very exceptional man to be really learned, or to be able to say anything really worth hearing, off his own subject. There are men who make a large portion of knowledge their province, but the majority of men cannot and should not aim at this. They should know one thing well, and in all else they should not be entirely ignorant.

This absence of entire ignorance is a far more valuable commodity than is usually supposed. It enables the man of affairs to consult specialists with advantage. Special knowledge is always available, if one knows how and where to look for it; but the man of complete ignorance is at the mercy of every charlatan; he puts his money into the wildest scheme, on the one hand, and on the other he fails to realise possibilities of sound application lying all about him. His enterprise and power may be great, but the blight of ignorance makes him useless; and it is just this blight which is endangering our continued industrial and commercial supremacy among the nations of the world.

We look to the new type of university now about to be created to remedy this state of things. If Birmingham succeeds in its high emprise, other great cities will follow suit. The experiment is one that is of interest to the whole British Empire, indeed to the whole Anglo-Saxon race.

In another article we may perhaps enter more into detail concerning some of the features of the scheme; but it is at present in such extreme infancy that its features are barely recognisable. It does not follow that what is immediately to the front is in reality the most important or the most characteristic.

(*To be continued.*)

## *THE STEADYING OF SHIPS.*[1]

THE evolution of the modern flat-bottomed merchant vessel, with its midship section of approximately rectangular form, from its old pointed-bottomed prototype, with deep central keel, has been a necessary result of commercial competition. The naval architect is called on to increase the carrying capacity of his vessels to the utmost extent, and a limitation is imposed on their draught of water by the limited depth of harbours, docks, rivers and, last but not least, ship canals. The old central keel has had to disappear in order that the extra foot or two of displacement might be utilised for the carriage of cargo, and a substitute has had to be found for it by the attachment of "bilge-keels" or side keels projecting from the ship at the only places where they could be placed without taking up valuable space—namely, at the two rounded-off corners of the rectangular section.

The efficiency of bilge-keels in modifying the rolling oscillation of ships seems to have been for some time a debated point among naval architects, and the experimental fact that the extinction of oscillation produced by these keels may in some instances be many times—possibly as much as ten times—that which would be inferred from determinations of the resistance of a paddle oscillating in water certainly appears at a first glance paradoxical. On reading Mr. Luke's paper in the *Transactions* of the Scotch Shipbuilders, and subsequently Sir William White's account of his experiments on the *Revenge*, it occurred to me that the properties of discontinuous fluid motion, so long a favourite study among mathematicians, might be put to a useful purpose in explaining the high resistances to rolling observed with the use of bilge-keels. So far from these resistances being in contradiction with the principles of hydrodynamics, they appeared to be to a large extent in conformity with our theory of free stream-lines, and this view has been borne out by subsequent calculations, certainly to a far greater degree than I at first anticipated.

According to hydrodynamical theory, if a solid body is set moving through or rotating in an unlimited mass of perfect fluid previously at rest, the motion will continue indefinitely, provided that the body has no sharp edges or corners projecting into the fluid, and that the velocity does not exceed certain limits. The motion involves no continuous expenditure of energy, and if the solid is brought to rest, the fluid will come to rest, and the energy which was expended in starting the motion will be recovered. If, however, the body has any sharp projecting edges, the fluid is unable to flow continuously round these, and discontinuous motion is set up, a mass of dead water being dragged along behind the projecting edges, and this dead water being separated from the moving fluid by a "surface of discontinuity" in crossing which the velocity changes abruptly. In this case the fluid motion is not destroyed when the solid is brought to rest, and energy is absorbed by the fluid. The theory of discontinuous motion is the basis of the well-known calculations of the resistance experienced by a plane lamina moving through a liquid, originally due to Kirchhoff, and subsequently developed by Lord Rayleigh, Love, Michell and others.

The case of a ship floating in water rocking from side to side differs from these ideal cases in the properties (1) that waves are produced on the surface, (2) that water is not a *perfect* fluid; so that energy is being continuously absorbed by wave-formation, and by the viscosity of the water. If the ship has no sharp keels projecting into the water, these are the only causes which retard the rolling of the ship, but as soon as keels are attached discontinuous motions are set up, which involve a further absorption of the energy of rolling, and the oscillations subside much more rapidly. If we imagine the ideal case of a ship floating in a perfect liquid, the surface of which is coated with a perfectly rigid sheet of ice entirely preventing any waves from forming, but just allowing free play for the ship to roll, the oscillation would continue indefinitely, provided the ship had no sharp projecting keels. If, however, bilge-keels were attached, the oscillations would gradually die down, the energy of rolling being absorbed by the production of discontinuous motions, and being transformed into kinetic energy of the liquid.

The object of this investigation is to show that the efficiency of bilge-keels in modifying the rolling of ships may be greatly increased by the action of the sides of the ship itself, and is so increased in a ship of section approaching to a rectangular form, provided that the bilge-keels are attached at the protruding corners of the section. This increased efficiency is due to two causes:—

---

[1] Abstract of a paper read before the Institution of Naval Architects.

(1) The rocking of the ship produces currents in the water, which flow round the corners in the opposite direction to that in which the ship is rolling, thereby increasing the pressure on the bilge-keels.

(2) The discontinuous motion past the bilge-keels alters the distribution of pressure against the sides of the ship, and the differences of pressure thus produced have a moment always tending to retard the rolling motion.

*The effect of stream-line motions.*—Consider a cylinder of section, such as represented in Fig. 1, rotating in fluid about an axis through its centre O. It is known that the fluid displaced by the motion of the cylinder will flow past its protruding corners B, D in the opposite directions to that in which the cylinder is moving; while at the points A, C, E the fluid will be moving in the same direction as the cylinder. Hence if a small lamina representing a bilge-keel be placed at B or D, it will encounter a current of liquid flowing in the opposite direction to that in which it is moving, and the pressure on the lamina will be correspondingly increased.

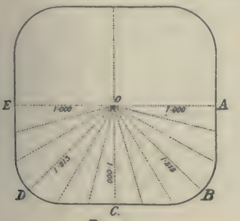

FIG. 1.

I made several calculations to form some estimate of the increases produced by these counter-currents on the resistance experienced by a suitably placed bilge-keel, assuming the resistance to vary as the square of the relative velocity. Taking certain sections more or less approximating to the form of a square with rounded corners, in a section where the greatest radius OB exceeded the least radius OA by 13 per cent., the resistance was increased, owing to this cause, by about 36 per cent.; while in the section actually represented in Fig. 1, OB exceeded OA by 21 per cent., and the resistance on a lamina at B came out 67 per cent. greater than it would be if the lamina had only to encounter the relative velocity of the fluid due to its own motion.

In these cases the fluid was supposed to be indefinitely extended. To estimate the influence of surface-conditions *without taking account of waves*, I next considered the case of a cylinder partially immersed in a liquid bounded by a rigid horizontal plane, the cylinder itself rocking about an axis in the plane of the surface. The form chosen for the section of the submerged portion was roughly suggested by a diagram of the ship *Revenge*, and the counter-currents past the protruding corners were found to be sufficient to more than double the resistance on a suitably placed bilge-keel.

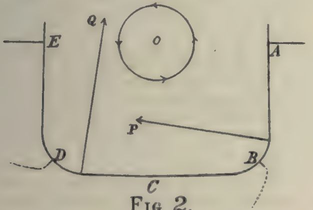

FIG 2.

*The effect of pressure-variations against the sides of the ship.*—The resistance on a lamina moving in fluid is due to the pressure being greater on the front than on the back of the lamina, this difference of pressure being the result of the discontinuous character of the fluid motion. When the lamina is attached to a ship as a bilge-keel, this difference of pressure also extends along the sides of the ship, the pressure in front of the bilge-keel being greater than behind it. Whether the pressure in front is increased or the pressure behind is decreased, or both of these effects take place simultaneously, is unimportant, for we may on each of these hypotheses represent the effect by an excess of pressure on the portions in front of the bilge-keels as compared with the portions behind.

Now let Fig. 2 represent a diagrammatic section of a ship approaching to a rectangular section, with bilge-keels at its protruding corners, B, D. Then if the ship be rolling about its centre of gravity, O, in the direction of the circular arrow, the greater pressures in front of the bilge-keels will be distributed over the segments AB and CD, and, as indicated by the arrows P and Q, their moments about O will be in the direction opposed to rotation. When the ship rolls in the opposite direction, the greater pressures will be on the segments BC and DE, and their moments will again tend to retard the rolling. In this way the pressures on the sides of the ship will materially assist the bilge-keels in steadying the ship.

To test the extent to which the pressure on the sides of the ship is likely to be modified by the presence of the bilge-keel, I examined the case of a fluid flowing along a plane, AB, with an edge, BC, projecting at right angles to it (Fig. 3). If from B there be measured off on BA a length = ·927 BC approximately, the thrust on this portion of BA is equal to the thrust on BC, and the average pressure on this portion is therefore a little greater than the average pressure on BC. If, again, we measure off on BA a length = 2·042 BC, the thrust on this portion is equal to twice that on BC. Speaking in general terms, we may say that the pressure is greater along BA than along BC, and that it does not fall off rapidly along the arm BA. If the arm BA, instead of being straight, bends away from BC like the curved side of a ship, we should expect the pressure on it to be even greater than in the case considered. These considerations led me to consider the results of supposing the bilge-keels to produce on the segments in front of them (AB and CD of Fig. 2) uniform increases of pressure equal in intensity to the average pressures on the keels themselves. Applying this hypothesis to a ship, the details of which were kindly furnished me by Dr. Elgar, I found that the total retarding moment came out to be about 3·9 times the retarding moment on the bilge-keels alone. This result, taken in conjunction with the previous result that the currents past the sides of the ship may double the pressure on the bilge-keel, shows that there is nothing paradoxical in the supposition that bilge-keels may have eight times the efficiency in extinguishing oscillations that would be inferred from experiments made with a simple paddle moving freely in fluid.

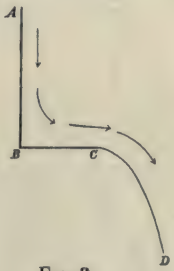

FIG. 3.

We learn from Sir William White that in the case of the *Sultan* the agreement between Mr. Froude's estimate of the resistance to rolling, based on the coefficient of resistance of a lamina, and the experimental facts was very close indeed. But the midship section of the *Sultan* was very much more nearly circular than that of the other ships experimented on. For a circular section there would be no counter-currents producing increased resistance, nor would the changes of pressure against the sides of the ship possess any retarding moment.

There are many further points connected with the investigation which want of space prevents us from discussing here. One such point is the fact that the rolling motion is not steady, but oscillatory, and, therefore, account must be taken of the pressures involved in producing changes of motion, in consequence of which the pressures differ from those which would exist at any instant if the motion were steady. These pressures, which I have called the "$d\phi/dt$ pressures," after the term which produces them in the hydrodynamical equation, are completely modified in their action when continuous motion is replaced by discontinuous motion, but their effect can only be discussed from general principles. Other points are the effect of the ship's forward motion in increasing the steadying action, and the influence of bilge-keels in modifying pitching and in improving the steering of ships; the two last effects are further simple consequences of the properties of discontinuous motion.

We have seen that the action of bilge-keels in steadying a ship is largely modified by the actions of the sides of the ship, and is much augmented when the keels are placed in a suitable position; and it is interesting to notice how the exigencies of trade, while they have necessitated the removal of keels from the middle line of the ship to the sides, have brought about such a change in the form of the section as to render the new position by far the most effective. In the old pointed-bottomed ship, the central keel was the best, as it not only intercepted the currents flowing round the bottom in each swing from side to side, but also produced a difference of pressure on the two sides whose moment was always opposed to rolling. In the modern flat-bottomed ship of rectangular section a central keel would be unfavourably placed for this purpose, as not only would the water tend to flow in the same direction as that in which the ship is rolling, producing a diminished pressure on the keel, but the differences of pressure on the sides of the ships would have a moment tending to diminish the resistance to rolling. The favourable position now commonly assigned to the bilge-keel is calculated to render its addition to ships of the greatest value in increasing their steadiness.

G. H. BRYAN.

## THE "ORTHOSTIGMAT" LENS.

A SPECIMEN of the new series of lenses issued under the joint auspices of Messrs. Beck and Steinheil, has been tested and examined by us. The lens is of the rectilinear symmetrical type with two equal combinations, each consisting of three elements. It is by special construction of the surfaces of these components that the remarkable qualities claimed for, and undoubtedly possessed by, the new lens are attained. The great drawback to the best of the old type lenses was the curvature of field, and it is only in recent years that the discovery of the new varieties of glass has made it possible to correct this, and at the same time perfect the corrections for spherical aberration and astigmatism. The result of the process is that each component of the lens is made up of a positive meniscus, with a double convex lens cemented on one side of it and a double concave one on the other. The centre positive lens will consequently have a lower power than the two outer ones.

When it is understood that each of the twelve surfaces involved in the complete lens is worked with such accuracy that an error of 1/40,000th of an inch is inadmissible, the increased price, compared with the old types of lenses, is amply accounted for in the superior product obtained.

We have tested the lens, which is of about 4¾ inches solar focus, and are quite satisfied that it fulfils to a high degree of perfection the claims made for it by the makers. Although the lens is listed for ¼ plate, the circle of good definition is much larger, and with a stop of *f*/16 excellent definition was obtained over the whole of a ½ plate. The lens at its greatest rapidity works at *f*/6·3, and at this aperture the definition appears very perfect over an area 4¼ inches square. The makers call attention to the special attempts they have made to eliminate astigmatism, and it is not until an oblique pencil falls considerably beyond the listed angle that any distortion shows itself. To make this clearer, let the image of the sun, moon, a star, or any distant object, be focussed at the centre of the plate, and then the camera so tilted that the image falls gradually away to the extreme corner. The slightest distortion can be at once recognised in this manner. With the lens in question no distortion was evident until the image was received at an angle of about 30 degrees from the axis, and for another 10 degrees further the resulting astigmatism, although present, was much less than is present closer to the axis in a rectilinear of the ordinary type. So that for an angle of view of over 60° the new lens is practically non-astigmatic at the large aperture *f*/6·3. This will recommend it especially for all process and copying work, where critical definition and speed are primary necessities. A word should be said concerning the focussing with these new lenses. This adjustment must be critical, as an almost imperceptible displacement of the plate will suffice to throw it out of the focal plane sufficiently to destroy the definition, and so create false impressions of the capabilities of the optical system. For all such work, therefore, only perfectly rigid apparatus is permissible.

Another important qualification of the lens is its comparative freedom from chromatic aberration, in virtue of which it will be useful for work connected with colour photography, obviating the laborious and uncertain corrections which are necessary in such work with the ordinary lenses, whose chromatic aberrations are only suppressed for the blue and yellow. Critical tests of this correction have not been possible, but sufficient have been made to show that the outstanding error is small.

On account of their covering power, the smaller sizes will be found excellent for low-power microphotography. The new lenses are obtainable with foci varying from 3½ in. to 23½ in., covering plates from 3¼ in. square to 28 × 24 inches.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The Romanes Lecture will be delivered by Dr. James A. H. Murray on Friday, June 22, upon "The Evolution of English Lexicography."

Sir William Thiselton-Dyer, F.R.S., has been made a permanent elector to the Sherardian Professorship of Botany, in succession to the late Prof. Bartholomew Price.

The Statute instituting Diplomas in Geography has been approved by Convocation, and is to remain in force until October, 1904.

The extensive bequest to the University under Mr. Fortnum's will has made an enlargement of the Ashmolean Museum necessary. The cost is estimated at 1500*l*., and towards this sum Brasenose College has offered a contribution of 500*l*.

At Merton College there will be an election to a fellowship on October 6, after an examination in Animal Physiology and Animal Morphology. Candidates are requested to inform the Warden by September 10 of their choice between these two subjects, and to submit, if they wish, original papers or memoirs.

At a meeting of the Oxford University Junior Scientific Club, held on Wednesday, June 6, Sir John Burdon Sanderson, F.R.S., gave an account of the method he has been lately employing for producing tetanus in muscle, by means of telephone currents produced by musical sounds, showing how the results bear on the vexed question of the inherent rhythmicality of muscle and nerve-cell. The lecture was illustrated by experiments.

At a meeting of the above club held on Friday, June 15, Mr. T. C. Porter, of Eton College, described the growth of the shadow of the Peak of Teneriffe, as witnessed from the summit of the mountain at sunrise and sunset, and its gradual eclipse by the shadow of the earth. He showed photographs taken at the time, and explained how by means of an ordinary watch and pair of opera glasses a rough value of the diameter of the earth might be deduced.

Mr. A. F. Walden, New College, made a preliminary communication to the club on the theory of labile hydrogen atoms.

CAMBRIDGE.—The researches of Mr. J. C. McLennan on electrical conductivity in gases traversed by kathode rays, and of Mr. R. L. Wills, of St. John's College, on the magnetic properties of iron as influenced by temperature and the presence of other elements, have been approved by the Degree Committee as qualifying for the B.A. degree.

In the Natural Sciences Tripos, which is now the largest of the Honour Examinations, forty men and three women are placed in the first class of Part I. In Part II. fourteen men and no women obtain first-class honours.

At St. John's College the following awards in natural science were made on June 18. Foundation Scholars continued or elected: Lewton-Brain, May, Adams, Ticehurst, Fletcher, Browning, Wakely, Gregory, Williams, Harding, Hepworth, Pascoe, King, Macalister, Mitchell. Exhibitioners: Crocker, Denham, Simpson, Balls. Hockin Prizeman (for electricity): Browning. Engineering Scholar: Paton.

THE attention of teachers and others engaged in schools is directed to the appeal made by Prof. Karl Pearson in our correspondence columns. Observations of the physical and mental characters of children are required, and measurements of the head, in order to provide material for an investigation of heredity upon which Prof. Pearson is engaged. There should be no difficulty in obtaining the co-operation of masters and mistresses in schools in this work, for the observations and measurements can be made with very little trouble, and they are of as much interest from an educational point of view as they are to biological science.

## SCIENTIFIC SERIAL.

*Bulletin of the American Mathematical Society*, May.—The number opens with four papers read before the Society at the dates annexed: On the geometry of the circle, by Dr. V. Snyder (December 28, 1899); isomorphism between certain systems of single linear groups, by Prof. L. E. Dickson (February 24); the Hessian of the cubic surface ii., by Dr. J. I. Hutchinson (February 24); and note on the group of isomorphisms, by Dr. G. A. Miller (February 24). These papers are short and, in the main, continuations of work previously published by the authors.—Prof. F. S. Woods contributes an interesting sketch of a German translation, by F. Engel, of two articles by Lobachevsky, with the titles "Ueber die Anfangsgründe der Geometrie" and "Neue Anfangsgründe der Geometrie mit einer Vollständigen theorie der Parallellinien." The reviewer's conclusion is that, "while it is remarkable that the solution of a two-thousand-year-old problem should be given almost simultaneously by three men, it should be remembered that these three were not the only mathematicians who had worked upon the problem. More than one had missed the solution by a hair's breadth only; Lobachevsky, Bolyai and Gauss succeeded in finding it."—Other notices are Vogt's "Algebraic solutions of equations," by J. Pierpont; the elements of the differential and integral calculus, based on the work by Nernst and Schönflies (translated by W. A. Young and C. E. Linebarger), by L. E. Dickson; and E. Pascal's "Die Variationsrechnung," by J. K. Whittemore.—University and general mathematical information come into the "Notes" and "New Publications."

## SOCIETIES AND ACADEMIES.

### LONDON.

**Royal Society**, April 5.—"The Kinetic Theory of Planetary Atmospheres." By Prof. G. H. Bryan, F.R.S.

The application of the kinetic theory to the atmospheres of planets dates from the paper of Waterston, who gave an investigation based on the then only possible assumption of equal velocities for all molecules, an assumption since known as Clausius' law. Of later papers reference is due in especial to Dr. Johnstone Stoney's memoir "Of Atmospheres on Planets and Satellites" (*Trans.* R Dublin Soc.), in which the test of permanence of a gas in the atmosphere of a planet is made to depend on the ratio of its velocity of mean square to that relative velocity which would enable a suitably projected body to escape from the planet's attraction. If it be admitted, as Dr. Stoney assumes, that helium cannot exist in our atmosphere, it follows that vapour of water cannot exist on Mars.

The author's object has been to investigate the logical conclusions obtained by applying the Boltzmann-Maxwell distribution to the atmospheres of planets. In 1893 calculations were made, having special reference to the absence of atmosphere from the moon, but these took no account of axial rotation. When this cause is taken into account, the distribution of coordinates and *relative* velocities of the molecules is found to be the same as if the planet were at rest, and "centrifugal force" applied to the system. The surfaces of equal density are of the forms originally investigated by Edward Roche, of Montpellier, and they cease to be closed surfaces when passing to the outside of the point on the equatorial plane where centrifugal force just balances the planet's attraction. Calling the surface through this point the "critical surface," the density of molecular distribution over this surface must be very small to ensure permanence. The ratio of the density at the planet's surface to the density at the critical surface has been called the "critical density ratio," and the author calculates its logarithm for particular gases at different temperatures on the various planets. The use of this logarithm has the advantage that the calculation can at once be extended to any gas at any temperature.

The high value obtained in the case of helium, considered in reference to the earth, appears to afford abundant proof that if helium existed in our atmosphere it would possess a very high degree of permanence at ordinary temperatures. To test this point further, a calculation is made of the total rate at which molecules would flow across the critical surface, this rate being regarded as a superior limit to the rate at which the planet would lose its atmosphere, since it takes no account of molecules which describe free paths beyond the limit and fall back again. To further exhibit the results in a tangible form, the rate of flow is estimated by the number of years in which the total amount of gas escaping across the critical surface would be equal to the amount of the gas in a layer covering the surface of the planet to the depth of 1 cm. This measure is independent of the actual quantity of the gas under consideration existing in the atmosphere, since, if this quantity be increased, the rate of flow across the critical surface and the amount of gas present in the surface layer 1 cm. thick will be increased in the same proportion.

If a gas of molecular weight 2, such as helium, be supposed to exist in the earth's atmosphere, the loss in question would occupy $3{\cdot}5 \times 10^{36}$ years at $-73°$ C., $3 \times 10^{19}$ years at 27°, $8{\cdot}4 \times 10^{10}$ years at 127° C., $6 \times 10^{6}$ years at 227° C., and 222 years at 327° C.

If we halve the absolute temperatures, we have the conditions applicable to hydrogen, the losses in question therefore taking place in $8{\cdot}4 \times 10^{10}$ years at $-73°$ C., $6 \times 10^{5}$ years at $-23°$ C., and 222 years at 27° C.

For water vapour on Mars, the corresponding results are $1{\cdot}2 \times 10^{33}$ years at $-73°$, $1{\cdot}9 \times 10^{16}$ years at 27°, $2{\cdot}4 \times 10^{9}$ years at 127°, $4{\cdot}3 \times 10^{5}$ years at 227°, and 106 years at 327°.

These figures indicate that helium cannot practically escape from our atmosphere at existing temperatures, nor can vapour of water escape from the atmosphere of Mars. A leakage may, and undoubtedly does, take place, which may appear considerable when estimated by the number of actual molecules escaping, but it is wholly inappreciable relative to the mass of gas left behind.

At a future time it is proposed to examine the corresponding results, based on the hypothesis that the atmosphere of a planet is distributed according to the adiabatic instead of the isothermal law.

"On the Weight of Hydrogen desiccated by Liquid Air." By Lord Rayleigh, F.R.S.

In recent experiments by myself and by others upon the density of hydrogen, the gas has always been dried by means of phosphoric anhydride; and a doubt may remain whether, on one hand, the removal of aqueous vapour is sufficiently complete, and on the other, whether some new impurity may not be introduced. I thought that it would be interesting to weigh hydrogen dried in an entirely different manner, and this I have recently been able to effect with the aid of liquid air, acting as a cooling agent, supplied by the kindness of Prof. Dewar from the Royal Institution. The operations of filling and weighing were carried out in the country as hitherto. I ought, perhaps, to explain that the object was not so much to make a new determination of the highest possible accuracy, as to test whether any serious error could be involved in the use of phosphoric anhydride, such as might explain the departure of the ratio of densities of oxygen and hydrogen from that of 16 : 1. I may say at once that the result was negative.

Each supply consisted of about six litres of the liquid, contained in two large vacuum-jacketed vessels of Prof. Dewar's design, and it sufficed for two fillings with hydrogen at an interval of two days. The intermediate day was devoted to a weighing of the globe *empty*. There were four fillings in all, but one proved to be abortive owing to a discrepancy in the weights when the globe was empty, before and after the filling. The gas was exposed to the action of the liquid air during its passage in a slow stream of about half a litre per hour through a tube of thin glass.

I have said that the result was negative. In point of fact the actual weights found were $\frac{1}{10}$ to $\frac{2}{10}$ milligrams *heavier* than in the case of hydrogen dried by phosphoric anhydride. But I doubt whether the small excess is of any significance. It seems improbable that it could have been due to residual vapour, and it is perhaps not outside the error of experiment, considering that the apparatus was not in the best condition.

May 31.—"Palæolithic Man in Africa." By Sir John Evans, K.C.B., F.R.S.

In April 1896, just four years ago, I ventured to call the attention of the Society (*Roy. Soc. Proc.*, vol. lx. p. 19) to some palæolithic implements found in Somaliland by Mr. H. W. Seton-Karr. In doing so, I pointed out the absolute identity in form of these implements with those from the valley of the Somme and numerous other pleistocene deposits in North-western Europe and elsewhere; and I cited others from the high land adjoining the valley of the Nile, and from other places in Northern and Southern Africa. I was at the same time careful to point out that though there could be no doubt as to this identity in form, no fossil mammalian or other remains had been found with these African implements. I did not, however, hesitate in claiming them as palæolithic.

Since the publication of my short note, an extensive collection of stone implements formed in Egypt by Mr. H. W. Seton-Karr has been acquired by the Mayer Museum at Liverpool. I have not had an opportunity of examining the specimens, but a detailed account[1] of them, with numerous illustrations, has been published by the Director of the Liverpool Museums, Dr. H. O. Forbes. The majority of the implements are of Neolithic Age or even of more recent date, and with the account of these I need not here concern myself; but the author is at considerable pains to dispute my view that the instruments of palæolithic forms belong to the Palæolithic Period. As he says, Mr. Seton-Karr's statement that he sometimes found spear-heads "on the ground surrounded by a mass of flakes and chips as though the people had dropped their work and fled," is very suggestive and important. He adds, however, that "one such occurrence is almost sufficient in itself, I venture to think, to disprove the high antiquity claimed by Sir John Evans for these implements."

Were it certain that the so-called spear-heads were really of palæolithic form, and had the flakes and chips been fitted on to them so as to reconstitute the original blocks of flint, as has been done in the case of undoubted palæolithic specimens by Mr. Spurrell and Mr. Worthington Smith, the question would still remain to be discussed as to the condition of the localities in relation to subaërial denudation.

It is, however, hardly necessary to discuss these points, as some recent discoveries made in Algeria will, I venture to think, go a long way towards settling the question. I propose, therefore, very briefly to state their nature. About sixty miles to the south-west of the town of Oran, and about ten miles to the north of Tlemcen, on the plateau of Remchi, about a mile to the south of the River Isser, lies a small lake known as Lac Karâr. It occupies a depression in lacustrine limestone of comparatively recent geological date, superimposed on beds of Lower Miocene Age. The level of the water, which is some 15° C. warmer than that of the ordinary springs of the district, and appears to be derived from some deep-seated source, seems to be about 600 feet higher than that of the River Isser. The lake originally filled a much larger part of the depression than it does now, and from its old bed a considerable amount of material has of late years been extracted for the Service des Ponts et Chaussées. This material consists of sand and gravel rich in iron pyrites, in the midst of which lie, pell-mell, bones of animals and stone implements fashioned by the hand of man.

These have for some years been diligently collected by M. Louis Gentil, a geologist, and form the subject of a memoir that has just appeared in *l'Anthropologie* (Tome xi.), by my friend M. Marcellin Boule, of the Galerie de Paléontologie at the Jardin des Plantes, Paris. Some 200 specimens of implements have been submitted to him, of various sizes, and all or nearly all of well-known palæolithic forms, including several with a broad chisel-like end, of which examples have been found in the laterite of Madras and the gravels of Madrid. They are for the most part formed of an eocene quartzite, though some smaller specimens of the type known as that of "le Moustier" are formed of flint. The *facies* of these latter is not so distinctly palæolithic as that of the former, of which some, through the kindness of M. Marcellin Boule, are exhibited.

The most important part of the discovery is that which relates to the mammalian remains found with the implements. These are of elephant, rhinoceros, horse, hippopotamus, pig, ox, sheep, and certain cervidæ. I will not detain the Society with the details given in M. Boule's memoir, but I may call attention to the fact that the elephant is not the African elephant, but one more nearly related to the quaternary or even pliocene elephants of Europe, to which the designation Atlanticus has been given. Some teeth seem closely allied to those of *E. meridionalis* and even *E. armeniacus*. Having regard to the whole fauna, M. Boule arrives at the conclusion that it is identical with that of the fossiliferous deposits of Algeria, which from their topographical or stratigraphical characteristics have been assigned to the Quaternary or Pleistocene Period. He also cites other instances in Algeria, such as Ternifine and a station near Aboukir, in which palæolithic implements have been found associated with the remains of a similar pleistocene fauna.

Altogether, these recent discoveries in Northern Africa tend immensely to strengthen my position with regard to the truly palæolithic character of the implements found in other parts of that vast continent, and I am tempted to bring for comparison some few specimens from South Africa. One of these, found by Mr. J. C. Rickard at the junction of the Reit and Modder twenty years ago, is almost indistinguishable from those of the Lac Karâr, as is also one from the valley of the Embabaan in Swaziland. But the most remarkable is an implement of typically palæolithic character found in 1873 under 9 feet of stratified beds at Processfontein, Victoria West, by Mr. E. J. Dunn.[1] May the day be not long distant when researches for the implements of palæolithic man may again be carried on, and trenches be dug in South Africa for peaceful instead of warlike purposes.

**Anthropological Institute**, June 5.—Mr. C. H. Read, President, in the chair.—Dr. J. G. Garson explained in detail the metric system of identification of criminals which is in use in this country. This system, which is a modification of the Bertillon system employed in France, consists in measuring as accurately as possible certain dimensions of the individual, and classifying them, according as they prove severally large, medium or small, in such a way that the search for any single set of measurements at the central office is curtailed to the utmost. Finger prints are used, as an additional proof of identity, on the back of the card which carries the record of the measurements. The paper was illustrated by diagrams and examples of the measurements and of the instruments which are employed; and was followed by a discussion.

June 12.—Mr. C. H. Read, President, in the chair.—The secretary exhibited, on behalf of Mr. H. Swainson Cowper, a primitive figurine from Adalia in Asia Minor, which presented analogies with the "owl-faced idols" found on the site of Troy by Dr. Schliemann.—Mr. B. H. Pain read a paper on Eskimo craniology, in which he stated that from observations on a number of living Eskimo, lately in London, he had been enabled to extend the comparisons instituted by Virchow between the dimensions of the head and those of the skull in this race. Reference was incidentally made in the paper to the collection of Eskimo crania at Cambridge (of which a descriptive note was published in the *Journal* of the Anthropological Institute, 1895), as well as to the large collection of crania of Greenlanders in the Anatomical Museum at Copenhagen. The paper was fully discussed by M. J. Deniker, Dr. Garson, Mr. Duckworth and Mr. Shrubsall.—Mr. W. L. H. Duckworth read a paper on the skeletal characters of the Mori-ori of the Chatham Islands. The result of his observation and measurement of ten skulls and two complete skeletons of Mori-ori (from the Chatham Islands) is a general corroboration of the earlier results of Turner (*Challenger* Report) and Scott (*Transactions* of the New Zealand Institute) as to the characters of the skeletons of these Pacific Islanders. Special notice was directed to the frequency of occurrence of osteo-arthritis, as evidenced by the condition of the sacrum, innominate bones and femora especially, and to the rare form of occipito-atlantic articulation in one of the specimens. The paper was followed by a discussion.—Mr. J. Gray gave a summary of the anthropometric survey conducted by Mr. James Tocher and himself in East Aberdeenshire, and exhibited diagrams showing the relative frequency and the local distribution of various types of complexion, &c.—A paper, by Mr. D. MacIver, on recent anthropometrical work in Egypt, was taken as read.

---

[1] *Bull. Liverp. Mus.*, II., Nos. 3 and 4 (Jan. 20); NATURE, vol. lxi. April 19, p. 597.

### EDINBURGH.

**Royal Society,** June 4.—Prof. M'Kendrick, Vice-President, in the chair.—Dr. R. Stewart McDougall read a paper on the biology of certain species of *Pissodes* and *Scolytus*. *Pissodes* is a genus of Coleopterous insects very harmful to pine trees in Great Britain, the eggs being laid under the bark, and the grubs tunnelling in the Cambial layer. In working out the life-history of *P. notatus*, a pest on young pines, and of *P. pini*, which attacks chiefly grown trees, the author found that imagos could be obtained from March to November, and that breeding might take place from April to September inclusive. A remarkable feature was the long life of adult beetles of both sexes, with repeated copulation. Specimens of *P. notatus* had lived 22, 24 and 37 months, hibernating twice in the first two cases and three times in the last case. Marked adults kept in confinement, but otherwise in natural conditions, began hibernation in November, and appeared above ground again in the following March. *Scolytus multistriatus* attacks the elm—almost invariably dead or decaying trunks or branches. Attempts to develop the eggs in living trees had failed. The beetles are late swarmers, appearing chiefly in July. The generation is an annual one.—Sir John Murray read a paper on the physical, chemical, and biological conditions of the Black Sea. Certain peculiar features were pointed out, notably the presence of a cold layer at a depth of 50 fathoms, the deeper waters being warmer; the lack of vertical circulation, and the consequent stagnation of the deep waters, which can find no outlet through the comparatively shallow straits; the presence of sulphuretted hydrogen and the absence of oxygen in these depths; the absence of animal life there; and the deposit of carbonate of lime on the bottom. This carbonate of lime was not of organic origin, but was formed by chemical action, the sulphuretted hydrogen being one of the products. The special interest of the inquiry arose from the fact that in several of these particulars the Black Sea conditions differed fundamentally from conditions that obtained in oceans and other ocean-connected seas.

**Mathematical Society,** June 8.—Mr. R. F. Muirhead, President, in the chair.—The following papers were read:—(1) A general proof of the addition theorems in trigonometry; (2) a slight extension of Euler's theorem on homogeneous functions, by W. Edward Philip; note on proofs by projection in trigonometry and co-ordinate geometry, by Prof. Gibson.

### PARIS.

**Academy of Sciences,** June 11.—M. Maurice Lévy in the chair.—Reduction of certain problems of heating or cooling by radiation to the more simple case of heating or cooling of the same bodies by contact; heating of a wall of indefinite thickness, by M. J. Boussinesq.—On the radiation of uranium, by M. Henri Becquerel. The rays from uranium are deviable in a magnetic field, although on account of the comparatively feeble action of the uranium radiations, the time of exposure of the photographic plates has to be very long. Uranium salts treated with barium salts and a sulphate have their radioactivity reduced. The author has not been able to obtain an inactive uranium salt.—Researches on the pressures of saturated mercury vapour, by MM. L. Cailletet, Colardeau and Rivière. An experimental study of the vapour pressure of mercury from its boiling point up to about 880°. At the point where the pressure is about 160 atmospheres, the experiments were stopped by the iron tubes allowing the mercury to pass through them, thus rendering the study of the critical phenomena of mercury impossible. The pressures were read on a metallic manometer which had been directly calibrated against a mercury column, and the temperatures on a thermo-couple.—On the $\beta$-phenyl and $\beta$-benzyl-$\alpha$-alkoxy-$\alpha$-cyanoacrylic acids, by MM. A. Haller and G. Blanc. Starting with phenylacetylcyanacetic and benzylacetylcyanacetic esters, the silver salts are prepared and these treated with alkyl iodide. The esters so obtained are isomeric with the benzoylcyanacetic esters, and are clearly derivatives of crotonic acid.—Note on an earthquake in Mexico on December 19, 1899, by the French Consul in Mexico.—On a photograph obtained at the Observatory of Algiers during the total eclipse of the sun of May 28, by M. Ch. Trépied.—On the polarisation of the corona of the sun observed at Elche, by M. P. Joubin. The experiments of Prazmowski and Ranyard were confirmed. Further observations with a Bravois bi-plate showed that for all points of the sun's limb between the equator, and about 15° to 20° from the north solar pole, there was no elliptical polarisation. Above this, the colours of the two plates could be clearly distinguished.—The method of Neumann and the problem of Dirichlet.—On the class of primitive continuous finite groups of transformations of Lie, by M. Edmond Maillet.—On the logarithms of the algebraical numbers, by M. Carl Störmer.—On the angular points of solubility curves, by M. H. Le Chatelier.—On the electrical distribution in a Hertz resonator in activity, by M. Albert Turpain.—Permanent modifications in metallic wires and variation of their electrical resistance, by M. H. Chevallier.—On the kathode rays, by M. P. Villard. A study of the heating effect produced upon the kathode. The usual metal electrodes can be replaced by ordinary lamp filaments, the kathode in this case being rapidly raised to a white heat. The fall of potential necessary for the production of light by a filament in this way is much greater than when the carbon is heated by the ordinary Joule effect. — The campylograph, a curve-tracing machine, by M. Marc Dechevrens. A new method of producing Lissajous figures. Instead of being confined to compounding two rectangular motions only, the instrument can combine three simultaneous movements, two rectilinear and oscillatory, the third uniform and circular. Seventeen illustrations of the results obtainable accompany the paper.—Heat of solution of hydrogen peroxide. Thermal value of the hydroxyl group: influence of carbon and hydrogen, by M. de Forcrand.—On the direct production by the wet method of mercuric and mercurous iodides in the crystalline state, by M. F. Bodroux. Mercuric iodide can be crystallised in octahedra from boiling concentrated hydrochloric acid or from a solution of potassium iodide. A better method is to leave mercuric acetate in contact with methyl iodide. The substitution of mercurous nitrate for mercuric acetate yields large crystals of mercurous iodide.—On the impossibility of the primary formation of potassium chlorate obtained electrolytically, by M. André Brochet. The electrolysis was carried out in presence of large amounts of oxide of cobalt. Since hypochlorites are destroyed by this oxide, whilst chlorates are unaffected, only chlorate which has been formed by primary interaction of the ions will be found. Since no chlorate is produced under these conditions, it follows that in the electrolysis of alkaline chlorides, contrary to the hypotheses of Œttel, Haber and Grinberg, Forster, Torre and Müller, the formation of chlorate is never due to a primary action, but is always due to the intermediate formation of hypochlorites, even in a strongly alkaline medium.—On the decomposition of metallic chlorides, by M. Œchsner de Coninck.—Addition of hydrogen to acetylene in presence of reduced iron or cobalt, by MM. Paul Sabatier and J. B. Senderens. At 180° reduced iron causes the interaction of hydrogen and acetylene, ethane, ethylene, benzene and higher unsaturated hydrocarbons being produced. Cobalt under similar conditions gives a much larger yield of ethane compared with that previously noticed for nickel.—On a product of decomposition of a diiodhydrin of glycerol, by MM. E. Charon and C. Paix-Séailles. The substance formed by the elimination of hydriodic acid from the iodhydrin, $CH_2I.CHI.CH_2OH$, is $\beta$-iodopropionaldehyde, most probably the polymer $(CH_2I.CH_2.CHO)_3$.—Action of acetylene upon cuprous chloride dissolved in a solution of potassium chloride, by M. Chavastelon.—On acidimetry and alkalimetry in volumetric analysis, by M. A. Astruc.—Fixation of clay in suspension in water by porous bodies, by M. J. Thoulet. Analysis of marine deposits consisting largely of shells, showed great variations in the amount of clay present, and it appeared possible that this clay might have been abstracted from the water after the death of the animal by mechanical means. Experiments with powdered pumice stone and with wood charcoal confirmed this view.—Preliminary note on the decapod crustacea collected during the Belgian Antarctic expedition, by M. H. Coutière.—The embryos of mummy wheat and barley, by M. Edmond Gain. A microscopical examination showed that in spite of their external appearance of good preservation, the mummy cereals do not possess a cellular organisation compatible with germination.—The ratio of nitrogen to chlorides in the contents of the stomach during digestion, by MM. J. Winter and Falloise.

### ST. LOUIS.

**Academy of Science**, May 23.—A paper by Dr. Adolf Alt, entitled "Original contributions concerning the glandular structures appertaining to the human eye and its appendages," was presented by title.—Dr. M. A. Goldstein read a paper on the physiology of voice production, in which he discussed three essential factors in the production of voice—the motor force, the organ of sound, and the resonators.—Prof. F. E. Nipher read a short communication on the zero photographic plate, to which reference was made at the meeting of May 7 (see pp. 62, 159). The zero plate is one upon which a photographic image has been made, but which will develop no image in a bath placed in light of given candle power, at a distance of one metre from the source. For example, if the developing bath is twenty centimetres from a sixteen candle lamp, a Cramer isochromatic plate, such as is called "instantaneous," held for ninety seconds at a distance of one metre from the lamp, will be a zero plate. With an opaque stencil over the plate when placed in a printing frame during the exposure, there will develop a positive of holes through the stencil, if the exposure is longer, and a negative if the exposure is shorter. If a fresh plate is exposed in our camera with full opening to a brilliantly lighted street scene for one minute, it will develop as a positive in that same bath. This time can be somewhat reduced, but the least time needed has not yet been determined. It is evident that part of this minute is used in producing a zero plate. It is furthermore clear that different parts of the plate will arrive at the zero condition at different times. The exposure may be arrested at a time when the strongly lighted white background of a sign-board will develop white as a positive, and when the black letters will also show white as a negative. It has been found that when a plate is uniformly exposed over its whole surface to the extent that nothing would have developed had it been covered by a stencil, this plate may then be placed in a camera and exposed in the ordinary way, and a perfect positive will develop in the bath to which it has been adapted. This preliminary spoiling of the plate for developing a negative is a very advantageous preparation for taking a positive. It shortens the time of exposure, and ensures that a positive shall be obtained over all parts of the plate. It is not yet known how short the camera exposure may be made, but the present indications are that they will be as short as those now made in the taking of negative pictures. It is currently believed by photographers that in a positive plate the object has "printed its picture" upon the plate. This appears to be a misconception of the process. It is true that in an exposure of long duration an image shows on the plate before it is placed in the bath. But this image is blackest where the light has acted most. It is a negative. This picture disappears in the developing bath when illuminated. The plate becomes perfectly clean. The positive picture then develops exactly as a negative would under ordinary conditions.—Mr. J. B. S. Norton presented some notes on the flora of the south-western United States

## CHRISTMAS ISLAND.

*A Monograph of Christmas Island (Indian Ocean); Physical Features ana Geology.* By C. W. Andrews, with descriptions of the Fauna and Flora by numerous contributors. Pp. xv + 237. (London: Published by order of the Trustees of the British Museum, 1900.)

TILL 1887 Christmas Island, which is situated in the Indian Ocean nearly a degree to the south-south-west of Batavia, was scarcely known, even by name, to the average Englishman, and only the low-lying shore had been visited by explorers; the steep cliffs, together with the forest with which the island is clothed, forming a barrier which had hitherto prevented access to the central plateau. In that year the Commander of H.M.S. *Egeria*, with the assistance of a landing party, succeeded in cutting his way into the interior; and two years later the island was leased by the British Government to a trading company. Since it contains an area of about forty-three square miles, and appears never to have been inhabited by aboriginal tribes, it presented a most favourable opportunity for studying the fauna and flora of an oceanic island of considerable size situated at no very great distance from a considerable land-mass—the Sunda Archipelago. Down to the time mentioned, it appears, indeed, to have been the largest uninhabited tropical island extant; and as the discovery of valuable deposits of phosphates in the interior indicated that its pristine conditions would soon be rudely disturbed, it was evident that if a biological survey was to be undertaken at all, there was no time to be lost. Fortunately, Sir John Murray interested himself strongly in the matter, and it was eventually arranged that Mr. C. W. Andrews, of the British Museum, who is both a geologist and a zoologist, should undertake the work. He accordingly spent ten months on the island during the years 1897–98; and the present volume, in which he has had the assistance of a number of specialists, is the result of his labours.

As is evident by their permitting a member of their staff to undertake the task, the Trustees of the British Museum gave their support to the exploration; and it is a matter for congratulation that they have seen fit to publish the results in the same form as the Museum "Catalogues." A wise liberality has been exercised in the matter of illustration, the plates (some coloured) being numerous, while a considerable number of reproductions from photographs are given in the text. These latter have, however, received but scant justice at the hands of the printer; and it is, indeed, with some surprise that we notice the volume bears the name of a local firm of printers.

Situated at a distance of over 190 miles from the nearest land, with the intervening ocean attaining a depth of more than three miles, Christmas Island appears to have derived its limited fauna from the Sunda Archipelago, of which indeed it probably once formed a part. The length of its isolation is, however, indicated by the circumstance that four out of its five indigenous mammals are peculiar species, the fifth—a Shrew—being a local variety of an Assam and Tenasserim form. The majority of the few land birds are likewise distinct, the most striking being a Goshawk (*Astur natalis*), an Owl (*Ninox natalis*), and a White-eye (*Zosterops natalis*), specimens of all of which were first collected by Mr. J. J. Lister during a flying visit to the island in 1890. As regards the fauna generally, it exhibits no greater evidence of affinity with that of the Mentawei chain of islands, running parallel with Sumatra and Java, than with that of the two islands last named. And the hypothesis that Christmas Island formed the termination of a "Mentawei Peninsula" must accordingly be given up.

One of the main objects of the exploration of the island was to ascertain whether its geological structure would throw any further light on the vexed question of the origin of atolls. As the result of his observations, Mr. Andrews is led to believe that, from the absence of a sufficient thickness of reef-limestone, Christmas Island, although originally an atoll, could not have been formed in the manner required by the Darwinian theory, as the amount of subsidence which has taken place would have been quite insufficient. That a certain amount of subsidence may have occurred in the early history of the island, Mr. Andrews considers to be quite possible.

> "It may, of course, be objected," he writes, "that Christmas Island was never a typical atoll, and to this objection no answer is possible; but since it can be shown that at one time it must have consisted of reefs and islands approximating very nearly to those seen in atolls which are regarded as typical, the determination of the nature of the foundations upon which these reefs and islands rested is at least a step in the right direction. . . . In this case the basis of the island is almost certainly a volcanic peak, the foot of which is now some 2400 fathoms below the level of the sea, and that on its summits and flanks great accumulations of Tertiary limestones have been deposited, and in some cases are interstratified with the products of the eruptions, probably for the most part submarine, which took place from time to time. The oldest of the volcanic rocks are trachytic, the newer basaltic. The last of the eruptions was accompanied by the formation of thick beds of volcanic ash, and it is upon these that the great mass of the Miocene (Orbitoidal) limestones rests."

The occurrence of such a thickness of Tertiary deposits (ranging from the Eocene or Oligocene upwards) is unknown in any other oceanic island. It is important to notice that these rocks, allowing for a difference in the proximity of land at the time of their deposition, are very similar to those of South Java; but the author considers that there are difficulties in believing that the two series of sediments were deposited in a continuous area, as this would involve great local dislocations. Accordingly the volcanic peak theory is adopted in preference to such a view.

In speaking of elevation and depression, the author is careful to guard himself by stating that such terms are merely used in relation to the sea-level; and it would appear, from reading between the lines, that he is rather in favour of an actual alteration of the sea-level in these districts. It may further be inferred that he does not intend his conclusions as to the mode of origin of Christmas Island to affect the case of other atolls, his idea apparently being that all atolls are not of precisely similar origin.

The rocks which have brought Christmas Island into the most prominent notice are the thick beds of nearly pure lime phosphate capping several of the higher hills. It is inferred that this deposit has been formed by the action of beds of guano on limestone forming the summits of the low islets presumed to have existed previous to the first elevation of the present island. Another phosphatic bed is considered to have been produced by guano acting on volcanic ash. It is for the purpose of working these phosphates that the island has been leased by a commercial company.

Although the greater part of the volume is of a highly technical nature, it must not be inferred that this is the case with the whole of its contents. As an example of its lighter side, the excellent account of the habits of the Frigate-bird may be cited. These birds, which form the main support of the present colony of the island, are of an inquiring and fearless disposition.

> "The usual way of obtaining them is," writes the author, "for a man to climb into the topmost branches of a high tree near the coast, armed with a pole eight or ten feet long and a red handkerchief. The latter he waves about, at the same time yelling as loudly as possible. The birds, attracted by the noise and the red colour, swoop round in large numbers, when they are knocked down with the long pole. In this way sufficient birds to supply the small colony with food can usually be obtained in an hour or two; occasionally, however, in unfavourable states of the wind, they are difficult to procure."

From first to last, the exploring, the collecting, and the descriptive and literary portions of the book have been thoroughly well carried out. And, despite the fact that no far-reaching or epoch-making discoveries in either zoology, geology, or distribution have been made, all concerned in the production of the volume before us (save the printer) are to be heartily congratulated on the manner in which they have executed their respective tasks. R. L.

---

## A NEW WORK ON SILVER.

*Metallurgy of Lead and Silver*. Part ii. Silver. By Henry F. Collins. Pp. 352. (London: Griffin and Co., Ltd., 1900.)

WE recently had occasion to notice the first volume of the present work, and to speak favourably of its merits. We are pleased to find the second portion equally good. It has been a source of great regret that the distinguished master of metallurgy, the late Dr. Percy, did not live to complete his projected work on Silver, instead of leaving what has been termed a splendid fragment: and as no book claiming to give a full account of the metallurgy of the subject has been published since, we cordially welcome the advent of a further contribution. It is perhaps unnecessary to point out how closely interwoven is the metallurgy of lead with that of silver, or to state that a full treatise on silver cannot be written without considerable reference to lead; and when one author is competent to deal with both branches of the subject, it affords the best means of imparting a sound knowledge of these metals. In the present case we have this additional advantage, that the editor is an authority on all questions relating to the nature and properties of silver, together with that of assaying. The immense importance of silver in the economic relations of the United States is well known, and many attempts have been made to introduce similar relations into this and other countries; hence it may be considered one of the most important metals known to mankind. The present work is not an exhaustive treatise on silver, and is evidently intended chiefly for those who are connected with the extraction of the metal from its ores. Those ancient methods which are fast becoming obsolete have not escaped notice; for, while they may not possess much practical value at the present time, their chemical and educational value is not to be despised. Numerous references to original sources of information are given throughout the volume, and this will enable the reader to obtain fuller information than is given here. The method of procedure in special works, such as that of matte smelting at Sunny Corner (p. 268), is described at some length with clearness and precision. The author has followed the same plan as in his first volume, of economising space by giving details of the practice at different localities in the form of tabular statements. This should prove useful for reference and comparison. The book is divided into four main sections, dealing respectively with silver and its ores, amalgamation, lixiviation, and smelting processes. Of these the chapters relating to lixiviation and blast furnace smelting are the best, as they appear to be the branches with which the author is most familiar. The hyposulphite leaching process is described in a more lucid and methodical manner than we have seen elsewhere, and the advantages and disadvantages of calcium sulphide are admirably compared on p. 197. A chapter is specially devoted to hyposulphite leaching practice, in which is given details of plant, mode of working, advantages and disadvantages of lixiviation, cost, and examples of the Russell process in various localities. Data as to cost and results at mills using the Patera and Russell processes respectively are given in the form of tables on pp. 224 to 227. A serviceable chapter on the refining of lixiviation sulphides concludes the section. The fourth section, dealing with the extraction of silver by smelting processes, contains a considerable amount of information in a condensed form. The table of comparison of various systems of smelting is instructive and helpful. The construction of furnaces is made clear by the aid of figures, drawn to scale. The arguments in favour of the hot blast for smelting mattes are pertinent and convincing. Several well-compiled tables are included in this chapter. Pyritic smelting receives only a brief notice in Chapter xv., as this subject has been partly dealt with in the first volume. The subject of matte smelting in reverberatories for silver-copper ores is next considered, and the characteristics of the method, with the points of difference from blast furnace practice, are pointed out. This kind of information is often of great moment to the practical man, who has to decide on the most economic method to adopt in special cases. The final chapters deal with the treatment of argentiferous mattes, which generally require a preliminary concentration to eliminate some of the lead and iron. In some cases a direct method may be adopted, and information is here given for that purpose. The Bessemerising of copper mattes is briefly described. Silver-copper smelting and refining is limited in its application to ores comparatively free from sulphur, arsenic, and lead, and therefore but little used. The plant employed is specified and illustrated by diagrams and tables. The book concludes with a short account of the various wet methods used for argentiferous slimes. The author's attempt to cover the ground embraced by such a wide subject within a moderate compass will, with the aid of tables and summaries, prove most valuable both to practical men and to students.

## OUR BOOK SHELF.

*The History of Language.* By Henry Sweet, M.A. Pp. xi + 148. (London: J. M. Dent and Co., 1900.)

There are few living scholars who are so well qualified as Dr. Sweet to write a thoroughly comprehensive introduction to the science of language. He is, as is well known, one of the foremost European authorities on phonetics: but at the same time he is a profound and original thinker on those psychological aspects of linguistic science in which few phoneticians take any interest. And while possessing a competent knowledge of Indogermanic comparative philology in its latest developments, he is preserved from the narrowness of view of the mere Indogermanist by having made a practical study of Arabic, Finnish and Chinese. Notwithstanding its small size, this "primer" is a very remarkable book. In completeness of outline, it is superior to any elementary manual of the subject known to us; and it is no mere arid skeleton, but contains a good deal of novel and interesting illustration of the principles expounded. Perhaps it is not quite so easy to master as a "primer" is usually expected to be. Although strictly elementary, in the sense that it assumes no previous philological knowledge on the reader's part, it does undoubtedly demand considerable power of close attention and some training in habits of scientific thought. It will therefore probably be less acceptable to absolute beginners than to those who have already some general knowledge of the subject and desire to render their conceptions of it more systematic and precise. Even by advanced philological scholars it may be studied with interest and profit.

The contents of the book may be said to consist of three portions: an exposition of the general principles affecting the development of language, an outline of the history of the Aryan family of languages, and a statement of the author's views as to the exterior affinities of Aryan and the locality in which it was developed. Perhaps the third part is somewhat out of place in an elementary book, but it is at any rate interesting. Dr. Sweet's hypothesis is that primitive Aryan arose in Scandinavia out of a mixture of the language of Ugrian conquerors with that of the aboriginal population among whom they were absorbed. This is not now such a startling heresy as it would have been a few years ago, though it is not likely at present to find a ready welcome from Indogermanists. The apparent affinities between Aryan and Ugrian certainly seem too striking to be due to mere coincidence, but it is a long step from this admission to the acceptance of the definite theory here propounded. The writers who have hitherto advocated somewhat similar views have always discredited their case by their ignorance of philology and their lack of scientific caution. It is to be hoped that Dr. Sweet will give to the world a full exposition of the grounds on which his conclusions are based. Whether he succeeds in the establishment of his particular thesis or not, he can hardly fail to make a valuable contribution towards the ultimate solution of the question.

*Micro-organisms and Fermentation.* By Alfred Jörgensen. Pp. xiii + 318. (London: Macmillan and Co., Ltd., 1900.)

The study of the biology of fermentation has made considerable progress in recent years. The knowledge that has been gained of the nature and mode of action of the living agents in question is mainly due to the efforts of foreign observers. Through the investigations of Pasteur, and most notably of Hansen, the subject became a recognised branch of methodical and practical inquiry. To be in a position to employ the essential and to exclude the deleterious agents in a fermentative process is to substitute scientific for haphazard methods. This, briefly put, is the aim of technical mycology, and the gain to a given industry is considerable, as *e.g.* in brewing and distilling operations. Of the books dealing with micro-organisms and fermentation, Dr. Jörgensen's has long occupied a leading position, and hardly requires an introduction to the specialist. The new edition just issued has been completely revised, and the English translation has been well done by Dr. A. K. Miller and Mr. A. E. Lennholm. Dr. Jörgensen's reputation as a teacher and investigator, as well as his intimate association with Hansen, place this work above the ordinary run of text-books. The first chapters deal with the methods of microscopical and physiological examination of micro-organisms, and the methods for obtaining and utilising pure cultures of the useful races of saccharomyces are described. The examination of water and air is next dealt with—a subject of importance on account of the injurious organisms that may exist in the air and water of a brewery. The chapter on bacteria is somewhat incomplete. The technical mycologist has commenced to study the bacteria more closely, and a fuller account of this branch of the subject will be found in Lafar's book. An interesting account is given of the alcohol-forming bacteria, and of certain symbiotic ferments, *e.g.* Kephir and the ginger-beer plant. The moulds of importance in technical work are fully dealt with.

Of recent work, Buchner's "Zymase" is shortly alluded to; but more mention might have been made of Calmette's investigations at Lille and Sèclin upon the symbiotic action of moulds and yeasts in the alcoholic fermentation. The account of the alcoholic ferments in Chapter v. is naturally the main and distinctive feature of this work, and it will be particularly valuable to the English reader on account of the lucid description it contains of Hansen's investigations upon yeasts. The various species of bottom and top fermentation yeasts of interest to the brewing chemist are fully dealt with. The final chapter is devoted to the application of the results of scientific research in practice. The value of the book is added to by a number of illustrations and a very full bibliography. As an introduction to the morphology and biology of the alcoholic ferments, Dr. Jörgensen's work leaves little to be desired, and constitutes a valuable complement to the text-books which deal mainly with the chemical side of the subject.

A. M.

*Photography in Colours.* By R. C. Bayley. Pp. 74. (London: Iliffe, Sons and Sturmey, Ltd., 1900.)

This little book is practically a reprint of a series of articles by the author which have already appeared in a photographic periodical, but the subsequent revisions and convenience of reference occasioned by their collection under one cover should render them more serviceable. The general principle has been to avoid technicalities and purely executive details, aiming rather to give a lucid explanation of the principles governing the various processes, which may be understood by readers not necessarily acquainted with photographic manipulation.

The opening chapters introduce the elementary ideas of the nature of colour and the undulatory theory of light. Following these is a chapter on the Lippmann process, this being the only direct process having a purely physical origin.

The fourth chapter deals with the principles of colour vision, showing how the colour curves of red, green and blue sensitiveness are employed in deciding the screens used in the three-colour photographic process; two processes of this type, founded by Ives and Joly respectively, being then fully explained.

The work is brought up to date by descriptions of Wood's diffraction grating process, and later improvements on the Joly process. A chapter is also devoted to three-colour photomechanical processes, and another to the method developed by Sanger Shepherd and others of producing lantern slides in three colours.

*Leçons nouvelles sur les applications géométriques du calcul différentiel.* Par W. de Fannenberg, Professeur à la Faculté des Sciences de l'Université de Bordeaux. Pp. 192. (Paris: A. Hermann, 1899.)

THE geometrical applications of the differential calculus, which are usually given in English treatises on the calculus, are mostly confined to plane curves. In these lessons, on the contrary, the author begins by assuming a knowledge of elementary analytical geometry of three dimensions, and proceeds at once to deal with subjects which occur in the latter part of an English text-book on solid geometry, in chapters on the general theory of curves and surfaces.

Thus we have sections on the descriptive properties of tortuous curves and curved surfaces, followed by sections on the metrical properties of tortuous curves, of ruled surfaces, and of surfaces in general.

The author's treatment of his subject is exceedingly clear and elegant, and there is considerable freshness of method. We may notice, in particular, the early employment of the six co-ordinates of a line; the use of the system of moving axes formed by the tangent, the principal normal and the binormal at a point on a curve; the systematic application of Gaussian curvilinear co-ordinates in developing the properties of the several classes of curves that may be traced on a surface.

In fact, a student will find here in small compass a pleasant introduction to some of the most powerful methods of modern analysis as applied to geometry, and if he proceeds afterwards to the "Leçons sur la théorie générale des surfaces," by Darboux, his study of that great classic will have been much facilitated.

*Elementary Illustrations of the Differential and Integral Calculus.* By Augustus De Morgan. New Edition. Pp. viii + 142. (Chicago: The Open Court Publishing Company. London: Kegan Paul and Co., Ltd., 1899.)

IT is nearly seventy years since De Morgan first published this tractate in the Library of Useful Knowledge. It was afterwards bound up with his large treatise on the differential and integral calculus, but the very inferior typography detracts much from the pleasure of perusing it there. In the present issue we have a very attractive reprint. Although there has been in recent years almost a superabundance of elementary treatises on the calculus, some of them not lacking excellent illustrations of the fundamental principles and processes of the subject, it may still be said that De Morgan's effort at popularisation remains the greatest of its kind, and far above all others in the philosophic spirit which animates it.

## LETTER TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### A Surface-Tension Experiment.

IF an unbroken vertical jet of falling water is allowed to impinge normally on a smooth circular disc, whose diameter is rather greater than that of the jet, then a phenomenon, illustrated by the accompanying photographs, is observed. These are one-ninth natural size.

A disc about 7 mm. in diameter was supported on the upper end of a knitting-pin, which was held vertically in a clamp.

A jet of water proceeding from a tube of 6 mm. internal diameter was directed downwards, so as to strike the disc centrally.

If the initial velocity of the jet is high, then an umbrella-shaped sheet is formed, which breaks up into a shower of drops at its margin. On diminishing the rate of outflow, the broken edge of the sheet gathers itself together and closes inwards until it reaches the upright supporting the disc, thus forming a completely closed pear-shaped surface (Fig. 1). The surface-tension of the falling sheet thus drags in the water radially, for if it were in separate drops these would describe parabolic paths.

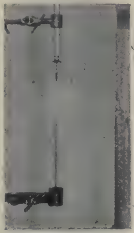

FIG. 3.
2100 c.c. per min

On further restricting the water supply there is, in general, a tendency for the surface to elongate and at the same time to contract laterally, thus becoming more spindle-shaped (Figs. 2 and 3). In this condition the figure is remarkably steady and well defined.

With a still slower stream of water (Fig. 4), the spindle reaches a certain critical length at which it first begins to oscillate vertically and to pulsate, and then a sudden constriction occurs causing the division of the spindle into two bubbles, one of which rushes down and the other up the vertical support.

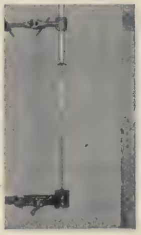

FIG. 4.
1600 c.c. per min.

FIG. 5.
1000 c.c. per min.

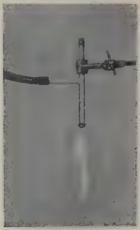

FIG. 6.

The latter bubble persists as a small conical figure immediately beneath the disc (Fig. 5).

Since there is an almost instantaneous transition from Fig. 4 to Fig. 5, it was not found possible to photograph any of the intervening conditions.

The length of the spindle in Fig. 4 (just on the point of undergoing segmentation) is about four times its diameter; a ratio which is considerably greater than in the three preceding figures, and which approaches that known to hold in the case of an unstable liquid cylinder.

The rate of outflow from the tube is in each case stated under the photograph.

The knitting-pin was then replaced by a glass tube, closed at its upper end, but connected below with a manometer, which was put into connection with the interior of the various bubbles by mean of a small hole previously blown in the side of the tube near its upper extremity. The pressure inside the bubbles was always found to be very nearly atmospheric, an excess of about 1 mm. of water being the greatest noted.

Another form of apparatus gave striking results.

A ⊣ tube was supported with the cross piece vertical, and the upper opening was closed with a cork into which a stiff wire was driven, so that it hung centrally, with its other end projecting a little from the lower opening of the tube.

The circular disc was attached to this projecting wire, and was then exactly in the path of the issuing stream of water which was admitted by the side tube.

By properly regulating the velocity of the water a series of surfaces similar to those produced by the former method can be obtained, but the adjustments are not so easily controlled (Fig. 6).

It is curious to note how the water constituting the walls of the bubble reunites into a single stream which falls from its base.

T. J. Baker.

King Edward's School, Birmingham, May 28.

## THE INTERNATIONAL CATALOGUE OF SCIENTIFIC LITERATURE.

In view of the proceedings at the recent third International Conference, of which the Acta are printed on another page, there can be little doubt that the ultimate execution of this important enterprise is now assured. Prior to the meeting, some of us, perhaps, vaguely feared that the foreign delegates would come prepared to suggest all sorts of difficulties, if not to announce the unwillingness of the countries they represented to take any part in the work; but nothing of the kind occurred: all came bent on securing success; not a word was uttered in depreciation of any of the proposals brought under consideration; and all present may be said to have taken an enthusiastic interest in carrying the proceedings to a satisfactory issue. Every one was of opinion that if a fair beginning can once be made, the importance of the work is so great; it will be of such use to scientific workers at large; that it will rapidly grow in favour and soon secure that wide support which is not yet given to it simply because its character and value are but imperfectly understood. Therefore, all were anxious that a beginning should be made.

It has been estimated that if 300 sets or the equivalent are sold. the expenses of publication will be fully met. As the purchase of more than half this number was guaranteed by France, Germany, Italy, Norway, Switzerland and the United Kingdom, the Conference came to the conclusion that the number likely to be taken by other countries would be such that the subscriptions necessary to cover the cost of the catalogue would be obtained.

The resolution arrived at after this opinion had been formed, "That the catalogue include both an author's and a subject index, according to the schemes of the Provisional International Committee," must, in fact, be read as a resolution to establish the catalogue.

Of the countries represented at the various Conferences, excepting Belgium, not one has expressed any unwillingness eventually to cooperate in the work. Unfortunately, neither the United States nor Russia was officially represented on the present occasion. The attempts that have been made to induce the Government in the United States to directly subsidise the catalogue have not been successful: but that the United States will contribute its fair share, both of material and of pecuniary support, cannot be doubted. There as here private or corporate enterprise must undertake much that is done under Government auspices in Europe. As to Russia, the organisation of scientific workers there has been so little developed that it is very difficult to secure their attention, and probably our Russian colleagues are as yet but very imperfectly aware of what is proposed. The importance of Russian scientific work is so great, however, that it stands to reason that it must be fully considered; and it may be supposed that Russia will join when she becomes acquainted with what is proposed and what is required of her.

A Provisional International Committee has been appointed, which will take the steps now necessary to secure the adhesion and cooperation of countries not yet pledged to support the scheme.

Originally, it was proposed to issue a card- as well as a book-catalogue, but on account of the great additional expense this would involve, and as the Americans in particular have not expressed themselves in favour of a card issue, it is resolved to publish the catalogue, for the present, only in the form of annual volumes.

From the outset great stress has been laid on the preparation of subject indexes which go behind the titles of papers and give fairly full information as to the nature of their contents. Both at the first and the second International Conference this view met with the fullest approval. Meanwhile, the action of the German Government has made it necessary to somewhat modify the original plan. In Germany, a regional bureau will be established, supported by a Government subvention, and it is intended that the whole of the German scientific literature shall be catalogued in this office; no assistance will be asked from authors or editors or corporate bodies. In such an office it will for the present be impossible to go behind titles; consequently, only the titles of German papers will be quoted in the catalogue. In the first instance, some other countries may prefer to adopt this course on the ground of economy. But in this country, at least, the attempt will be made to deal fully with the literature, and the cooperation of authors and editors will be specially invited. An author may not always be best able to judge which are the most important points in his paper to be noted in an index, but the experience gained in the Royal Society during several years past has shown that authors furnish most valuable information, and that their suggestions are easily reduced into shape. A full code of instructions for the use of the regional bureaux is now being prepared under the auspices of the Provisional International Committee.

The catalogue is to be published annually in seventeen distinct volumes. The collection of material is to commence from January 1, 1901. As it will be impossible to print and issue so many volumes at once, it is proposed to publish them in sets of four or five at quarterly intervals. During the first year, parts covering shorter periods will be prepared, so as to make the subsequent regular issue possible of volumes in which the literature published during a previous period of twelve months is catalogued. Valuable opportunity will thus be given from the outset of gaining experience both in the preparation and use of the catalogue.

That many difficulties will be encountered in carrying the work out cannot be doubted; but if scientific workers generally will but reflect on the inestimable value of accurate classified subject indexes, they cannot but see that it will be to their great advantage to do all in their power to further the enterprise. If the attempt fail, it will only be because those on whose behalf it is undertaken are blind to their own interests.

H. E. A.

## NOTES.

THE annual visitation of the Royal Observatory, Greenwich, by the board of visitors, took place on Tuesday last.

A SPECIAL joint meeting of the Royal and Royal Astronomical Societies is being held in the rooms of the Royal Society to-day, to receive preliminary accounts of the observations of the recent eclipse of the sun.

THE Nilson Memorial Lecture will be delivered by Prof. Otto Pettersson, of Stockholm, before the Chemical Society on Thursday next.

THE great kindness and attention shown oy the Alcalde and other authorities at Santa Pola to the astronomical party who went there to observe the recent eclipse, and to the captain and officers of H.M.S. *Theseus*, who conveyed the members of the expedition from Gibraltar, occasioned a very pleasing little episode. On leaving Santa Pola a donation of 10*l*. was collected, and left by Captain Tisdall with the Mayor for the benefit of the poor of the town. This gift was highly appreciated by the local authorities, and the amount has been distributed by a local committee. The children in the schools were not forgotten, and each of them received a packet of sweets and a memorial card relating to the eclipse and the visit of the expedition. We are also able to state that the Mayor of Santa Pola has received from the Spanish Government a decoration of the First Order of the Civil Administration. We heartily congratulate him on his new honour, which all who had any relations with him know was well deserved.

AT a public meeting recently held in Belfast, it was decided to renew the invitation to the British Association to visit Belfast in 1902, and a representative deputation was appointed to present the invitation at the forthcoming Bradford meeting of the Association. The last meeting in Belfast took place in 1874, and was under the presidency of Prof. Tyndall.

SIR WILLIAM MACCORMAC is to receive to-day the honorary degrees of M.D. and M.Ch. from the University of Dublin.

THE death is announced of Prof. Boutan, general inspector of public instruction in France. Prof. Boutan was one of the founders of the Société française de Physique, and was also the author, jointly with M. d'Almeida, of a treatise on physics.

THE death is announced of Dr. Karl Lange, professor of pathological anatomy in the University of Copenhagen; also of Dr. Wilhelm Kühne, professor of physiology at Heidelberg.

THE new physical laboratory at Owens College, Manchester, will be opened to-morrow by Lord Rayleigh. The new laboratory will have a larger floor area than that of any other similar institution in the world, with the exception of the Johns Hopkins and the Strasburg laboratories. Great efforts have been made to provide an equipment of the most modern apparatus for use in every branch of physical science, and to maintain conditions which shall ensure their being used to the best advantage. The research laboratories are to be an important feature of the new buildings, and should attract a large number of students. Another feature is the electro-technical wing, which is to constitute a John Hopkinson memorial, and will be formally handed over by the relatives of the late Dr. John Hopkinson, on the occasion of the opening ceremony. It is understood that Dr. C. H. Lees, formerly chief assistant lecturer in the physics department of Owens College, will occupy the post of assistant director of the new laboratories, under Prof. A. Schuster, the director, and that Mr. R. Beattie has been appointed lecturer in electrotechnics.

AT the conversazione to be held at the London Medical Graduates' College and Polyclinic on Wednesday, July 4, Prof. Osler F.R.S., of Baltimore, will deliver an address on "The Teaching of Practical Medicine," and the museum will be inaugurated.

THE annual general meeting of the Röntgen Society will be held on Thursday, July 5. The Presidential Address will be delivered by Mr. Wilson Noble.

THE second annual meeting of the Astronomical and Astrophysical Society of America is being held in conjunction with the meeting of the American Association at Columbia University. In addition to the papers to be presented, there will be discussions upon the following subjects:—The eclipse of May 28 last; Observations of Eros to be made at the next opposition; Spectroscopic determinations of motion in the line of sight.

AN important meeting of the Committee of the Liverpool School of Tropical Medicine was held on the 19th inst., when it was reported that the Government were co-operating with the School in the matter of the despatch of the Yellow Fever Expedition to America and Brazil, and that a letter had been received from the Marquess of Salisbury asking whether the Committee wished him to communicate with the British representatives in the countries to be visited by the expedition. The offer was gratefully accepted, and a further letter was received from Lord Salisbury saying that he had asked the British Ambassador at Washington and H.B.M. Consul at Para to obtain all possible facilities from the United States and Brazilian authorities respectively on behalf of the expedition. Official invitations for the expedition to visit Washington had been received from the heads of the medical departments of the U.S. army, and to visit Baltimore from the authorities of the Johns Hopkins University. As has already been stated in these columns, the expedition consists of Dr. Durham (Grocers Research Scholar) and Dr. Walter Myers (John Lucas Walker Student), both of Cambridge. The expedition, which started on Tuesday last, goes first to Canada, and then proceeds direct to Washington and Baltimore. After conferring with the bacteriological experts there, the expedition will go to New York, and sail from that port to Para. Subsequent movements will be guided by circumstances.

AT a dinner given last Monday in honour of the Yellow Fever Expedition, Mr. A. L. Jones, chairman of the school, announced his intention of giving 1000*l*. towards the erection of a Tropical Diseases Hospital in Liverpool in connection with the Royal Southern Hospital, to be associated with the name of Miss Mary Kingsley. It was also announced that Mr. Blaize, of Lagos, and Mr. John Holt, of Liverpool, had promised 500*l*. each to the same object. Two other subscriptions of 100*l*. each were announced.

THE Summer School of Medicine, which was to have been held at Cambridge from June 25 to June 30, has, unfortunately, had to be abandoned in consequence of the meagre number of acceptances received. The necessity for the taking of this step is the more to be regretted, as very careful preparations had been made to insure a successful session; demonstrations of the malarial and other blood parasites, and of the most recent work on cancer, had been arranged for, and in addition to these subjects lectures were to have been given by experts in their several lines of work upon various other matters of medical and surgical interest.

THERE are, it is estimated, about 400 lepers in France. They are scattered about in Brittany, in the Pyrenees, on the shores of the Mediterranean, and in Paris, where they number 150. Among the lepers there are missionaries and nurses who have fallen victims to their devoted care of sufferers in other countries, and officials and soldiers who have contracted the disease in the colonies. An anti-leprosy committee has, says the *British Medical Journal*, recently been formed on the initiative of Dom Santon, a member of the Benedictine Community of Ligugé, who is also a doctor of medicine, for the care of the lepers in France and the prevention of the spread of the disease. Dom Santon has for many years past devoted himself to the study of leprosy, travelling for that purpose in many parts of the world. After conference with the Council of Hygiene he has acquired a property in the Vosges, where he proposes to establish an asylum for lepers to be called the St. Martin Sanatorium. The plans have been approved by the French Government.

THE National Academy of Sciences of the United States has recommended to the trustees of Columbia University that the Barnard medal be given to Prof. Röntgen for his discovery of the X-rays. The medal, of gold, is awarded quinquennially to the person who shall have made such discovery in physical or astronomical science as, in the judgment of the National Academy of Sciences, shall be esteemed most worthy of the honour.

AN entomological expedition is to be sent into Southern Mexico this summer by the University of the State of Missouri. It will be in charge of Prof. J. M. Stedman, head of the Entomological Department, and will have for its object the making of a biological, largely entomological, survey of the region from Vera Cruz on the Gulf, which is in perpetual tropics, to the top of the volcano Popocatepetl, which is far above the perpetual snow line, and down to Acapulco on the Pacific. This will give all the temperature variations from perpetual tropics to perpetual snow, and will allow of the study of life zones under conditions not to be found elsewhere in North America. The collection will become the property of the University, which is to furnish half the expenses, the other half being borne by Prof. Stedman.

AN expedition, consisting of President Jordan and Mr. John O. Snyder, of the Department of Zoology in Stanford University, has sailed for Japan, for the purpose of making a collection of the fishes and insects of that country. Assistance will be given by other graduates of Stanford University at present resident in Japan.

IT is stated in *Science* that Mr. G. B. Gordon has secured the control of the ruins of Copan, and the lands pertaining thereto, for a period of ten years, with the right to make excavations and to remove to Cambridge, Mass., for preservation, a portion of the objects that may be found.

MR. O. A. TITTMANN has been appointed successor to Dr. H. S. Pritchett as superintendent of the United States Coast and Geodetic Survey, Dr. Pritchett having been elected president of the Massachusetts Institute of Technology.

THE American National Geographical Society's prizes for the best essays on Norse discoveries in America have been awarded to Mr. C. B. Dalton, of New York City, and Mr. K. F. Murray, of Norfolk, Va.

*Science* announces that a donor, who wishes to be anonymous, has presented to the American Museum of Natural History the collection exhibited by Messrs. Tiffany and Co. at the Paris Exposition, consisting of American and foreign cut and uncut precious stones and other objects. The value of the collection is estimated at over 50,000 dollars.

DURING the summer a station will be maintained on Lake Saranac by the New York State Museum, for the study of aquatic insects. The work will be under the direction of Dr. Charles Needham.

THE *Scientific American* states that a new species of petrel has been discovered on the Island of Kauai (Sandwich Islands) by Mr. A. Searle, of the Stanford University. Mr. Searle is also reported to have found on the same island a new species of seagull. He is about to go to Guam for the purpose of exploring that island, and to make a collection of birds and fishes for the Bishop Museum of Honolulu.

EXCELLENT results have been obtained by the French Government from experiments made with wireless telegraphy. The *Engineer* of June 15 says that the demonstrations showed that communication could be maintained, between ship and shore, to a distance of about sixty miles with comparative ease, only the height of the masts of the Government ship *Utile* preventing longer distances being attained. In consequence of these achievements the French Government have decided to equip their Mediterranean Squadron with the necessary apparatus.

WIRELESS telegraphy stations are, by the instructions of the Chief Signal Service Officer of the United States, to be established in the harbour of San Francisco, in Porto Rico and the Philippines.

AMONG the numerous congresses arranged to take place in connection with the Paris Exposition, in addition to those to which attention has already been called in these columns, may be mentioned the following, dealing respectively with:—Automobiles, on July 9; medical electrology and radiology, from July 27 to August 1; medicine, from August 2 to 9; physics, from August 6 to 11, and on the same dates, technical and industrial education; chemistry, from August 6 to 11; hygiene and demography, from August 10 to 17; hypnotism, from August 12 to 15; electricity, from August 18 to 25; prehistoric anthropology and archæology, from August 20 to 25; ethnology, from August 26 to September 1; railroads, from September 15 to 23; acetylene, from September 23 to 28.

IT is satisfactory to find that the present troubles in South Africa have not interfered with Museum progress in the larger towns of Cape Colony. From the *Report* of the Committee of the Albany Museum for 1899, we learn that it was expected the new buildings would be ready for opening about July 1.

A SEVERE thunderstorm occurred in London on the 25th inst., accompanied by heavy rain and hail. The weather had been very unsettled for some days, with gales on our exposed coasts. On the evening of the 24th a storm area lay off the north-west coast of Ireland; this subsequently took a somewhat unusual south-easterly direction. At 8 a.m. on the 25th the centre lay over the Midland Counties, and next morning had traversed the south-eastern part of the English Channel. The rainfall on the 24th and 25th amounted to about an inch in several parts of the United Kingdom. The temperature continues low for the season over the whole country.

TWO specimens of the egg of the Great Auk were sold by auction at Stevens's Rooms last week, and realised 315 and 180 guineas respectively. The more important of the two eggs is an unrecorded one from a French collection, and is described as the finest specimen known of a special type of marking. The price just obtained for it establishes a record, 300 guineas having, until this sale, been the highest amount ever received. About seventy-five eggs of the Great Auk are known to be in existence.

ACCORDING to *Science*, the Millinery Merchants' Protective Association of America has proposed to the various Audubon Societies of the country to cease killing or buying any North American birds, except such as are edible and killed in season, if the societies will undertake not to interfere with the use of these birds or with skins imported from countries not in North America.

The *Pioneer Mail* (Allahabad) of June 1, 1900, has an interesting article on the recent discoveries in the neighbourhood of the previously identified birthplace of Buddha. Mr. W. Peppé, owner of the Birdpur estate on the Nepal frontier, excavated in January 1898 a reliquary (stūpa) of Buddha, and found relics in a casket inscribed in characters not later than the third, and possibly even of the fourth, century B.C. During last winter Prof. Rhys Davids revisited the spot, and gave to the Royal Asiatic Society at its meeting in April last the result of his own local observations and examination of the relics, which is that they have a very fair title to be considered genuine remains of Buddha. These are stated to have been divided after the cremation into eight portions, and distributed amongst sections of the Śakya clan, which inhabited this region. The relics themselves are fully described and illustrated in the Royal Asiatic Society's *Journal* for July 1898, and further notices on the subject are to be looked for in forthcoming numbers of the same journal, and also (by Dr. Hoey) in the *Journal* of the Asiatic Society of Bengal. It is hoped that the Government of India may support Mr. Peppé in further excavations in this evidently promising locality.

The *Scientific American* for June 9 gives the following interesting particulars of a specially built train used on the Baltimore and Ohio Railway in a series of experiments upon the atmospheric resistance to railroad trains. The trial train was made up of six passenger coaches, such as are used on suburban service. They were provided with four-wheeled trucks, 33-inch cast-iron wheels, and 3¾-inch journals, and the total weight, exclusive of engine and tender, was 325,500 pounds. In preparation for the test all external obstructions were removed from the train. The roofs of the cars were arched; the windows set out flush with the sides of the cars; and the sheathing was laid lengthwise instead of perpendicularly as in other cars. The sheathing extended to within eight inches of the track and covered the trucks. Suitable openings permitted access to the axle boxes, and a sliding door led into the substructure at opposite sides of the car centre. When the cars were coupled, two diaphragms met and enclosed the space between the cars, from edge to edge of the roof line. The platform doors consisted of roller curtains which dropped to the steps and were flush with the sides. Flexible spring curtains completed the vestibule from the roof to the bottom of the car. When the train was coupled it presented the appearance of one long sinuous and flexible car. The tender was of peculiar construction, and continued the unbroken line from the engine cab to the baggage car, to which it was vestibuled. In its entire construction the train complied with the varied demands of practical operation. While the plans called for partial sheathing of the locomotive, it was decided to make the first tests with remodelled cars only, in order to prove how far the existing system of car construction is responsible for the atmospheric resistance of trains. The sheathed train, consisting of six cars and hauled by an engine weighing 57 tons, made the run of 40 miles from Baltimore to Washington in 37 minutes and 30 seconds. One mile was made in 40 seconds, and two miles in 81 seconds. From Beltville to College, a distance of 4½ miles, the time was 3 minutes and 10 seconds, a sustained speed of 85 miles an hour. By far the most remarkable run, however, was from Annapolis Junction to Trinidad, a distance of 20·1 miles in 15 minutes and 20 seconds, at an average speed of 78·6 miles an hour. The first seven miles of this run was up a grade from 25 to 55 feet to the mile, and it was covered in a fraction over 6 minutes; while the last 5 miles on the down grade from Alexander Junction to Trinidad was covered in 2 minutes and 55 seconds, a speed of 102·8 miles an hour. The locomotive used has cylinders 20 × 24, with four coupled 78-inch drivers. The boiler carried 165 pounds of steam. With ordinary firing the steam never dropped below 160 pounds during the entire run. The best time previously made on the line was a few seconds less than 39 minutes, on which occasion the train consisted of four Pullman cars hauled by the company's fastest and most powerful passenger engine.

The Report of the Kew Observatory Committee for the year 1899 has been published in the *Proceedings* of the Royal Society in the usual form. From January 1 last the Observatory was incorporated with the National Physical Laboratory, and will no doubt greatly extend its useful work. The Observatory Committee, as hitherto constituted, has ceased to exist, but the work of the Observatory will be carried on by the same staff as heretofore. During the past year the magnetic work is said to have been unusually onerous, as many colonial and foreign institutions have sent their instruments to the Observatory to be verified No very large magnetic disturbances were registered; the mean Westerly Declination was 16° 57′. The electrograph has worked in a satisfactory manner during the year, and, with the sanction of the Meteorological Council, the records for a complete year have been lent to Mr. C. T. R. Wilson, of Cambridge, for investigation. The verification of instruments of all kinds amounted to over 22,000, a falling off of nearly 2400 as compared with the work of the previous year. A seismograph has been in regular operation during the year; a disturbance was particularly noticeable on September 10.

The dynamical principle of atmospheric circulation is treated by Prof. V. Bjerknes in the *Meteorologische Zeitschrift*, 1900, iii., iv. Starting with the property that the circulation theorems of abstract hydrodynamics (according to which the circulation in any circuit formed by the same particles is constant) only hold good when the pressure is a function of the density alone, Prof. Bjerknes points out that in the atmosphere this condition is not satisfied owing to local differences both in the temperature and in the degree of moisture present in the air. Of these two causes the first seems to be the most important. The conception of "solenoids" is then introduced, a solenoid being an elementary unit tube bounded by pairs of consecutive surfaces of equal volume and equal pressure respectively. The fundamental proposition in connection with circulation asserts that the rate of change of the circulation in any circuit is proportional to the number of solenids enclosed by that circuit. A number of diagrams are given representing the cases of land and sea breezes, trade-winds, local upward currents, hill and valley winds, cyclones and anticyclones. The omission to take account of the extra complications arising from viscosity and terrestrial rotation probably prevents these investigations from being utilised for calculations in connection with weather prediction; and for this reason Prof. Bjerknes' theory must be rather regarded in the same light as other dynamical theories of physical phenomena, in which certain simplifications not occurring in nature are made in order to bring the calculations within the range of mathematical analysis. But it is only by the aid of such simplifications that order can be evolved out of the chaos of statistics furnished by the experimentalist.

An account of the seismological observatory of Quarto, near Florence, together with the observations of more than 170 earthquakes made during the meteoric year 1899 (November 1, 1898–October 31, 1899), is published by the director, Mr. D. R. Stiattesi, in the first *Bollettino Sismografico* of the observatory. Through the generosity of Count G. Bastogi, of Florence, this must be one of the most completely equipped observatories in Italy. It contains two Vicentini microseismographs (one with a mass of 500 kg. and a length of 9·28 metres), a pair of horizontal pendulums with mechanical registration, and a pair of geodynamic levels, besides a large number of seismoscopes and tromometers, all of Italian design.

IN the June number of the *Zoologist*, Mr. A. H. Meiklejohn raises the question as to the manner in which the cuckoo carries her egg when about to deposit it in the nest of the bird selected to act as foster-mother. It is commonly supposed that the egg is carried in the beak, and in Prof. Newton's edition of "Yarrell" several instances are quoted where observers state they have actually seen the *modus operandi*. Mr. Meiklejohn, who was fortunate enough to observe a cuckoo in the act of depositing its egg in a robin's nest, is, however, of opinion that the throat of the bird serves as the receptacle for the egg. He states that (1) the cuckoo was constantly opening her mouth during a preliminary encounter with the robins; (2) that the egg was certainly not laid in the ordinary way in the nest; (3) that the egg itself was slightly moist and sticky; (4) that the throat of the bird presented a slightly distended appearance, which might well have been due to the presence of the egg. It will be interesting to note what his fellow-ornithologists think of the author's explanation of the mystery.

IN American laboratories it appears that the place of the common frog is largely taken by the furrowed salamander (*Necturus maculatus*), which forms the general subject for anatomical investigation. Mr. W. S. Miller, assistant professor of anatomy in the Wisconsin laboratory, has accordingly undertaken to describe in detail the anatomy of this amphibian, and papers on its lungs, vascular system and brain appear in the latest issue of the *Bulletin* of the University. The author calls attention to the great amount of individual variation which occurs in the vascular system of *Necturus*.

IN a communication to the latest issue of the *Proceedings* of the Philadelphia Academy, Mr. Witmer Stone shows that the various species of eider-duck, as well as the red-breasted merganser, have a "summer moulting plumage" analogous to that assumed by the mallard after the breeding season. As in the last-named species, this plumage lasts only during the time when the birds are unable to fly, owing to the shedding of their flight feathers, and its dull coloration is doubtless for the purpose of rendering them as inconspicuous as possible during this period. The author calls attention to the circumstance that the feathers of this temporary dress, like those of the first plumage of all birds, are very inferior in their structure. The moulting plumage of the king-eider has hitherto been considered as the ordinary dress of immature birds.

IN a paper on mosquitoes, by Mr. W. R. Colledge, which appears in vol. xv. of the *Proceedings* of the Royal Society of Queensland, the author states that he has succeeded in keeping one of these insects alive for three weeks, and that Dr. J. Bancroft has had some in captivity for eighty or ninety days. Probably their ordinary full term of existence is three months. In cases where the application of kerosene is inconvenient, the introduction of a few minnows into the ponds or pools in which they breed will speedily lead to the destruction of the larvæ and pupæ.

THE origin and formation of the Red Sea are discussed in a brief article by M. A. Issel (*Bull. Soc. Belge de Géol.*, tome xiii. April). Following Suess, he considers that the lacustrine conditions of the Arabic depression ("Lacus Arabicus") were probably determined in late Miocene times. He maintains that then, or early in Pliocene times, the Nile, a mightier river than it now is, emptied its waters directly into the great lake, the outlet being an immense waterfall. Even in post-Pliocene times the Nile continued to send a portion of its waters into the Red Sea, although it had meanwhile formed new outlets into the Mediterranean area. Traces of this former fluviatile connection are furnished in the actual faunas of the two seas. The opening of the Straits of Bab-el-Mandeb was caused after a period of volcanic activity, the eruptions being succeeded by subsidence and by erosion of the barrier which separated the Red Sea from the Indian Ocean. It is remarked that the opening of the Suez Canal has sensibly affected the distribution of some forms of life.

IN a paper on the fruiting of the blue flag, or Iris, published in the May number of the *American Naturalist*, Prof. J. G. Needham shows that, in addition to the bees by which they are fertilised, the flowers of this plant are visited by a number of insects of other kinds. The visits of these latter appear for the most part to have been hitherto noticed; and as many of these illicit visitors are of no use for the purpose of fertilisation, the ill-adapted ones are, according to the author, habitually deceived by the flower itself as to its proper entrance. Of the various visitors, two small bees of the genera *Clisodon* and *Osmia* were thoroughly at home in the flower, alighting at the entrance and passing immediately down the narrow passage leading into the nectary, and as quickly emerging and flying off. On the other hand, numerous kinds of Syrphid flies spent a much longer time on the flower, which many of them visited only for pollen. Other visitors were certain small flower-beetles and weevils, which never by any chance succeeded in reaching the nectary.

TWO interesting lectures by Prof. D. T. MacDougal, delivered at the Woods Holl Marine Biological Laboratory, are reprinted from the *Bulletin* of the New York Botanic Garden. In his address on the "Significance of Mycorhizas" a general summary is given of our present knowledge of the occurrence of these organisms, both endotropic and ectotropic. All known species of mycorhizal fungi are stated to belong to the families Oomycetes, Pyrenomycetes, Hymenomycetes, and Gasteromycetes; and it is suggested that their further study and identification may result in a considerable increase in our knowledge of the physiology of vegetable life; and that their culture may not be without importance in the nutrition of a number of perennial flowering plants. The lecture on the "Influence of inversions of temperature, ascending and descending currents of air, upon distribution" is devoted to an explanation of the distribution of the flora in the United States, especially in the region of the great cañons.

APPENDIX III. for 1900 of the *Kew Bulletin of Miscellaneous Information* is entirely occupied with a list of the additions to the Library of the Royal Botanic Gardens, made during the year 1899

THE *West Indian Bulletin*, vol. i. No. 3, published in Barbados, contains the completion of the report on the papers read at the Agricultural Conference held in that island, and of the discussions arising out of them.

THE last two parts which have reached us of Engler's *Botanische Jahrbücher* (vol. xxviii. Hefts 1 and 3) are occupied entirely with the useful description and systematic papers which form so conspicuous a character of the work. Among those relating to flowering plants are the following, or instalments of them:—Compositæ of Ecuador, by Hieronymus; The flora of Central America, by Loesener; Classification of the Calyceraceæ, by Reiche; Revision of the genus *Linnaea*, by Graebner; African Verbenaceæ, Borragineæ, and Labiatæ, by Gürke; *Triplochiton*, a new genus of Malvales from the Cameroons, constituting the type of a new family, Triplochitonaceæ, by Schumann; Report of the botanical results of the Nyassa Lake Expedition, by the Editor. Herr Hennings and Dietel furnish respectively instalments of their papers on the Fungi and on the Uredineæ of Japan.

We have received a number of papers by different officers of the Observatory of Catania. Most of these we have noticed on their first appearance. Among the others, we may mention a valuable memoir, by Mr. S. Arcidiacono, on the eruptive period of Etna from July 19 to August 5, 1899, in which he points out the approximate coincidence of the great explosion on the former day with the total cessation of the flow of lava in Vesuvius and a strong earthquake in Latium, and also an interesting account of the history of the observatories of Catania and Etna.

The *Mittheilungen aus dem Roemer-Museum*, Hildesheim (No. 11, April 19), includes a paper, by Mr. A. R. Grote, on the phylogeny of the families of butterflies, with a genealogical tree. It is a continuation and amplification of previous papers on the same subject, published by the author in Germany and America, and is mainly based on neuration. Like many authors, Mr. Grote divides the butterflies into two main super-families, Papilionides and Hesperiades; but it will surprise many entomologists to find that all the butterflies except the true Papilionidæ are referred to the Hesperiades.

A new journal has been started in Berlin, the first number of which bears the title "Laboratorium et Museum," while in the second number the words "et Clinicum" are added. The journal is to be of an international character, and includes articles and notes in English, French and German. The title of the journal is sufficiently suggestive in itself of the contents, which comprise descriptions of new apparatus and reagents, methods of preparation, notices of new books, obituary notices, and lists of trade catalogues, of which the publishers will send copies on application.

Dr. Francesco Fossati has published in the *Memorie* del R. Istituto Lombardo a bibliography of the writings of Volta. Several such lists have already been published: one in 1813 by Prof. Configliachi, containing the titles of forty-four works; one in 1877 by Prof. Pietro Riccardi, containing sixty titles; while the collection procured by Antinori in 1816 contained sixty-seven writings. The present bibliography is partly the outcome of a suggestion made by Prof. Alessandro Volta, junr., at the Como Electrical Congress last year, and it contains the titles of 231 writings.

In the current number of the *Berichte* (p. 1569) Baeyer and Villiger describe some of the properties of the new hydride of benzoylsuperoxide, $C_6H_5CO\,O.OH$. The substance is obtained by the action of sodium ethylate upon benzoylsuperoxide,

$$C_6H_5CO.O.O.CO.C_6H_5 + NaOC_2H_5 = C_6H_5CO.O.ONa + C_6H_5CO.OC_2H_5.$$

The sodium salt of the new compound is formed together with ethyl benzoate. The ethyl benzoate is removed with ether, and the hydride of benzylsuperoxide separated by acidifying and extracting with chloroform. On distilling the chloroform, the hydride remains as a colourless crystalline mass, which melts at 41–43°. It is very soluble in the ordinary solvents, with the exception of benzene. The smell is penetrating and pungent, resembling, in the dilute state, hypochlorous acid, but not ozone. In its oxidising action on potassium iodide or aniline, and in its reducing action on permanganate, it stands midway between hydrogen peroxide and Caro's reagent (potassium persulphate dissolved in concentrated sulphuric acid). With benzoyl chloride it forms benzoylsuperoxide; with acetic anhydride, benzoylacetylsuperoxide. The oxidation of benzaldehyde to benzoic acid by exposure to air is shown to be due to he agency of this new compound,

$$C_6H_5COH + O_2 = C_6H_5CO.O.OH$$
$$C_6H_5CO.O.OH + C_6H_5COH = 2C_6H_5.COOH,$$

which is formed as an intermediate product.

The additions to the Zoological Society's Gardens during the past week include a Smooth-headed Capuchin (*Cebus monachus*) from South-east Brazil, presented by Mr. F. Wallace; an Indian Desert Fox (*Canis leucopus*) from Persia, presented by Captain D. J. Leiper; a Small Hill Mynah (*Gracula religiosa*) from India, presented by Captain R. York Heriz, R.N.; two Yellow-bellied Liothrix (*Liothrix luteus*) from India, presented by Miss Petrocochino; a Cockateel (*Calopsittacus novae hollandiae*) from Australia, presented by Mrs. Harry Blades; four Ring-necked Parrakeets (*Palaeornis torquatus*) from India, presented by Mr. J. M. G. Bate; three Chaplain Crows (*Corvus capellanus*) from Southern Persia, presented by Mr. B. T. Ffinch; two Green Lizards (*Lacerta viridis*), four Viperine Snakes (*Tropidonotus viperinus*), a Smooth Snake (*Coronella austriaca*), two Marbled Newts (*Molge marmorata*), European, presented by the Rev. F. W. Haines; an Ourang-outang (*Simia satyrus*, ♂) from Borneo, five —— Mole Rats (*Spalax* sp. inc.) from East Africa, a Grey Parrot (*Psittacus erithacus*) from West Africa, a Yellow-cheeked Amazon (*Chrysotis autumnalis*) from Honduras, nine Mountain Witch Ground Doves (*Geotrygon cristata*) from Jamaica, a Hocheur Monkey (*Cercopithecus nictitans*) from West Africa, seven Brazilian Tortoises (*Testudo tabulata*) from South America, five American Box Tortoises (*Cistudo carolina*) from North America, deposited; two Peba Armadillos (*Tatusia peba*) from South America; three Spotted Owls (*Athene brama*) from Madras; three White-throated Finches (*Spermophila albogularis*) from Brazil, a Thick-billed Seed Finch (*Oryzoborus crassirostris*) from South America, a White-eared Conure (*Pyrrhura lencotis*) from Brazil, a Loggerhead Turtle (*Thalassochelys caretta*) from the Tropical Seas, purchased; two Burrhel Wild Sheep (*Ovis burrhel*), a Thar (*Hemitragus enlaicus*), born in the Gardens; two Pied Mynahs (*Sturnopastor contra*), bred in the Gardens.

---

## OUR ASTRONOMICAL COLUMN.

**Astronomical Occurrences in July.**

July 3. 8h. 0m. to 9h. 11m. B.A.C. 4006 (mag. 5·7) occulted by the moon.
4. 1h. Mercury at greatest elongation (26° 2′ east).
5. Jupiter in conjunction with β Scorpii.
8. 11h. 24m. to 11h. 54m. δ Scorpii (mag. 2·5) occulted by the moon.
8. 13h. Jupiter 1° 35′ north of the moon.
9. 10h. 50m. to 12h. 2m. 24 Ophiuchi (mag. 5·6) occulted by the moon.
9. Pallas in opposition to the sun.
10. 10h. 18m. to 11h. 10m. 33 Sagittarii (mag. 6·0) occulted by the moon.
10. 12h. 19m. to 13h. 18m. $\xi^2$ Sagittarii (mag. 3·5) occulted by the moon.
10. 16h. Saturn 0° 48′ south of the moon.
14. 9h. 43m. to 10h. 17m. $c^1$ Capricorni (mag. 5·2) occulted by the moon.
15. Venus. Illuminated portion of disc, = 0·018. Mars = 0·948.
15. 8h. 29m. to 9h. 21m. κ Aquarii (mag. 5·5) occulted by the moon.
15. 10h. 11m. Minimum of Algol (β Persei).
16. 11h. 3m. 11h. 42m. 16 Piscium (mag. 5·6) occulted by the moon.
21. 13h. 2m. to 13h. 52m. 53 Tauri (mag. 5·5) occulted by the moon.
21. 14h. 53m. to 15h. 12m. D.M. + 20°, 751 (mag. 5·9) occulted by the moon.
25. Giacobini's comet situated close to α Cygni.
28. Epoch of the Aquarid meteoric shower (Radiant 340° – 12°).
31. Ceres in opposition to the sun.

The Next Total Eclipse of the Sun.—We have recently received *Nautical Almanac Circular* No. 18, issued under the superintendence of Dr. Downing. This pamphlet contains the local particulars of the next total eclipse of the sun, which takes place on May 17, 1901. From inquiries which have been made, it appears that the positions selected in the eastern portion of the shadow track are those which are most easily accessible. These are all situated in the Malay Archipelago, with the exception of Mauritius. The durations of totality at the various stations recommended are as follow:—

| Station. | Long. | Lat. | Duration of Totality. |
|---|---|---|---|
| | ° ′ | ° ′ | m. s. |
| Mauritius ... ... | 57 33·2 E. ... | 20 6 S. ... | 3 35 |
| Padang, Sumatra ... | 100 20·5 ... | 0 58 ... | 6 14 |
| Pontianak, Borneo | 109 20 ... | 0 1 ... | 5 40 |
| Fort Victoria, Amboyna .. ... | 128 11 ... | 3 41 ... | 4 15 |
| Port Moresby, New Guinea ... .. | 147 9 ... | 9 28 ... | 3 19 |

The elements on which the computations are based are those published in the *Nautical Almanac* for 1901. A map of the region is included in the circular, by the aid of which other stations than those specified may be selected if desired.

ANCIENT RECORDS OF METEOR SHOWERS.—In his report for the year 1899, M. D. Eginitis, director of the Athens Observatory, gives a short account of some ancient records of meteor showers which appear to be suggestively consistent with the constants of several conspicuous showers of present times.

A shower was mentioned by the patriarch Nicéphore as lasting all night, but no exact date is given. From the historical statements given, however, M. Eginitis traces the epoch as the autumn of the year 752. This would suggest it being a shower of Andromedes, and, in fact, counting from the conspicuous falls of Bielids in 1852, 1872 and 1892, the twenty years interval corresponding to three periods of the comet, it is seen that the year 752 would be in such a series. He thus considers this apparition of 752 to have been a Bielid shower of Andromedes.

Seven years previously to this, in 745, the appearance of a great comet was recorded by Théophane and Cédrinos.

It may be, however, that the showers of 1852 and later are not from the same swarm as the shower of 752, but that they are the products of slow but continual disintegration of the comet.

Another passage in Cédrinos describes a shower in 558, also occurring in the autumn. Apparently connected with this is the observation of a comet in 518, the interval being almost six times the periodic time of Biela's comet, so that here there would appear evidence of a second series of showers, connected with Biela's comet by similarity of period, but occurring at different epochs from the first series mentioned. The modern showers of 1798 and 1838 would fall in this second group.

Théophane in 763 and Domno Alberico in 1122 record falls of shooting stars in the month of April, and these would correspond to the present showers of Lyrid meteors.

A shower chronicled in April 1094 by Alberico cannot be at present connected with any known radiant.

## *A MODERN UNIVERSITY.*[1]

### II.

THE constitution of the new University of Birmingham is on the simplest and broadest lines, and appears to offer scope or great developments in the future, some of which can hardly be foreseen at the present time.

The movement for the foundation of a university arose out of the Mason Science College, founded by Sir Josiah Mason in 1875, just a quarter of a century ago; though it was not till five years later that the college was open to receive students. In 1892 an amalgamation was effected with the Queen's College Faculty of Medicine, and in 1897 the whole was incorporated as one body under the Mason University College Act. The Senate consists of twenty-seven members, and there are a large number of lecturers and demonstrators; but that it should have already developed into a university is a very remarkable fact, and a sign of great enterprise and energy on the part of the community among which the college has done its work; indeed, it is unlikely that this rapid development could have taken place unless it had been fortunate enough to secure the interest and personal influence of a prominent Minister of the Crown.

The Faculties of the University already provided for are science, arts, medicine and commerce, but provision is made for the addition of other faculties by Statute later on. Each faculty holds its own meetings, and is presided over by its elected dean.

The assemblage of professors constitutes the "Senate," as usual. The "Council," or acting governing body under the Court, consists of the deans of the faculties, five nominees of the Birmingham City Council, twelve members appointed by the Court of Governors, and lastly of the chief officials of the University, *i.e.* the Chancellor, the Vice-chancellor, the Pro-Vice-Chancellor, the Treasurer, the Principal, and the Vice-Principal. The Court of Governors is a very widely representative body, consisting of all the chief officials in the neighbourhood of Birmingham, the head-masters of the principal schools, ten of the Members of Parliament for the boroughs and counties in the Midland district, a nominee of each of the other English Universities (including the University of Wales), a member from each of the Midland County Councils, five nominees by the Birmingham City Council, certain named life governors and donors of certain sums, all the professors of the University, six persons elected by the Guild of Graduates, three by the Guild of Undergraduates, and eleven members appointed by the voluntary elementary schools of the neighbourhood.

It is hardly possible to imagine a wider basis of representation than the one adopted for the Court of Governors of this University.

Among the executive officers there is to be a Secretary, and also a Registrar appointed by the Council; the Vice-Principal and one of the deans, *i.e.* the Dean of the Faculty of Medicine, are likewise to be appointed by the Council. There is to be a Principal appointed by the Crown; there is also to be a Vice-Chancellor elected by the Court of Governors, and there is to be a Chancellor; the first Chancellor being the Right Hon. Joseph Chamberlain, and the first Vice-Principal Prof. R. S. Heath.

Concerning the objects to which all this machinery will be applied, no doubt a good deal will at the beginning be conducted on lines with which we are more or less familiar, though there appears to be no desire to imitate other universities, but rather a hope that it may be possible to strike out on a new line, and develop a broad system of national education suited to modern times, and to the practical requirements of life in an active city of the British Empire.

To this end a committee of inquiry was formed, and a deputation sent to various colleges and universities, chiefly in the United States and Canada, in order to study what was going on there. This body reported to the management committee connected with the establishment of the University of Birmingham, and their report constitutes an important and informing document. In it they say that:—

"Their object has been the teaching of science in its application to industry, and in the first place to the industries of the city and district, coupled with such technical instruction in handicrafts as will enable the students to complete their course in the university itself."

They classify the industries of the district as follows:—mining, metallurgy, engineering, and chemical trades, and non-metallic trades.

They recommend that there shall be chairs of mining, metallurgy, engineering, and applied chemistry. They further recommend that the students should be put through a very thorough course, consisting largely no doubt of a study of mathematics, physics, pure chemistry, and geology, as taught at present, but finishing with a specifically technical course, making it four years in all. A shorter course would likewise be permissible, but it appears would not lead to a degree.

They say the students should be divided into two classes, viz.:—

(1) "Those taking a four-years' course in mechanical (including electrical), civil or mining engineering, metallurgy or applied chemistry, who would study for a master's degree in their respective subjects. At the conclusion of this course facilities would be offered for further study and research to those who could give the time or should wish to proceed to the doctor's degree."

(2) "Those taking a course of from one to three years in any of the above subjects, with a view to the practical application of the teaching to a particular industry. With such students, less time could be devoted to theory, as attention would have to

---

[1] Continued from p. 186.

be concentrated on methods and results. Their work in these courses would be recognised by class certificates."

In addition to the professor of each technical subject there will be an assistant-professor and several instructors, each competent in a particular branch.

They indicate a block plan for the buildings required, their size and their suggested arrangement. These plans suppose a front of two storeys, containing the lecture rooms, library, museum, &c., and at the back a series of blocks, all on the ground floor, and intended for the various laboratories and workrooms which have been described in the report. These could be built to provide accommodation in the first instance for 200 day students, increasing afterwards to 500.

"The space occupied by these buildings, including the necessary yards and roads, a gymnasium, a director's house, and rooms for a caretaker, is about six acres. In view of the future of the university, a total area of not less than twenty-five acres should be provided."

The committee recommend that this land be taken in the outskirts of the city on a main line of, by preference, both rail and road, and they estimate the complete cost as follows :—

| | |
|---|---|
| Twenty-five acres of land and buildings ... | 80,000*l.* |
| Machinery, apparatus, and instruments ... | 66,000 |
| Fittings, utensils, lighting, and heating ... | 5,000 |
| Technical library ... ... ... ... | 1,500 |
| Museum ... ... ... ... ... | 500 |
| Director's house ... ... ... ... | 2,000 |
| Total ... | 155,000*l.* |

They estimate the cost of maintenance (including the staff) at 10,450*l.* per annum.

Thus the scheme is a very large one, but it is estimated that the fees from students will ultimately do a good deal towards covering the cost of maintenance.

The committee do not advise night classes, and in this we think they are wise; they consider that the already existing municipal technical school either does provide or might provide for the need these night classes are intended to meet, and they are sure that the curriculum they propose will absorb all the energies of the teaching staff when employed in the daytime only. They do not clearly indicate the training they propose for mining engineers, but for mechanical, electrical, and civil, they draw up a course the same in the first two years; in the third year the mechanical and electrical branch off on the one hand, and the civil on the other, while in the fourth year there is more specialisation, but not much distinction drawn even then between mechanical and electrical.

So far, the lines indicated are not very different from what is becoming customary, but they propose to attempt a Faculty of Commerce. Now the establishment of a great commercial school on serious lines is a new experiment, and has not yet been successfully tried anywhere. They propose a capital expenditure of 6000*l.* on class-room accommodation, together with books and apparatus, and an annual expenditure of 2200*l.* on a professor, an assistant professor, an instructor, and some special lecturers. We think that they will find that the addition of certain other chairs will be essential if a commercial faculty is to take its proper position, especially political economy and geography, probably law also. We do not see that any provision has been made for these three subjects. We regard a thorough course in political economy as essential to the well-being of a commercial faculty; and geography, treated completely, we regard as a much more important subject than the committee at present seem to realise.

The advisory committee enter further into the difficult question of commercial education. They say that modern languages should be learnt when quite young; which indeed is very true, but it seems to us a counsel of perfection. In practice we feel sure that modern languages would certainly have to form a considerable part of a scheme for commercial education.

Commercial arithmetic, they say, does not go far enough; and that also is extremely probable; but a training in elementary mathematics, beyond the immediately practical stage, would be of great advantage to the commercial man in many indirect ways.

As to geography, the committee think that the information is best obtained as wanted from books of reference and consultation with one of the touring agencies; but in this we entirely differ from them. To make proper use of books of reference some previous knowledge of the subject is necessary; and the earth, especially the portion accessible to trade, is not so big but that an adequate knowledge concerning its chief features should be acquired and possessed by a competent man of business, without having to refer constantly to others.

The committee, however, go on to recommend that, in addition to these things, instruction shall be provided in business organisation, the theory and principles of trade unions, associations, trusts, combinations and rings; that instruction shall be given in commercial law, likewise in accountancy, in shipping and railway practice, and in banking and exchange; and they say very wisely that "such knowledge as the foregoing is what is required in business, and is usually only learnt bit by bit at a heavy cost, so that the man of business has generally reached the limits of his working life before he has completed his commercial education, and owing to the want of a codified system business men continue from generation to generation to renew the mistakes of their predecessors, and to repeat their experiments, and after much tribulation to re-arrive at their methods, their rules and their conclusions."

They further indicate that this commercial education is not to be taken as a substitute for a more general education, but is to be a supplement to it. They say, "Students in the commercial education course should not be allowed to enter at too early an age. Twenty is quite early enough; and it would be most desirable that they should have taken a degree in Arts before studying for the commercial degree, and certainly the highest commercial degree should only be given to those already in possession of an Arts degree."

They hope (again in this case) that the fees from students may make it largely self-supporting, but we incline to think that they estimate the fees from students too highly. If they fix the fee for each student at 50*l.* a year, we fear that the expense will exclude a considerable number of those who might otherwise derive special benefit from the course proposed.

They realise that this attempt at a thorough commercial education is a new experiment, and one which, if successful, may have most important consequences on the commercial future of the country, and they conclude as follows:—

"There is no instance elsewhere of any course at once so complete and so valuable; there is not even, so far as your committee know, any university in the United Kingdom where there is a separate Faculty of Commerce, and as there has not yet been any effort to treat the subject with the thoroughness now proposed, so there is no means of estimating the extent to which advantage would be taken of such teaching. Your committee, however, point to the fact that a Faculty of Commerce so organised and based on the actualities of business experience, would at the present moment stand alone, and would therefore attract to the Birmingham University all who feel the need of such an education, and would also to a much greater extent create a new demand."

There is no doubt, however, that the Arts Faculty in general requires strengthening in many ways, the addition of new chairs being one of them; and unless this is done as soon as opportunity offers, the scientific and technical training proposed will not acquire its proper university status. The training of the students must not be limited to their immediate fancied needs; neither students nor their parents are the best judges of what is in the long run really desirable. A much broader training must be given in the university of the future than has been given in the university of the past. Depth without breadth has been the feature of some Honours schools; shallowness with athletics has been the feature of some Pass schools. The university of the future must mend all this, and secure that all its graduates without exception have had a broad training in many subjects—subjects lying in different departments of human knowledge; so that they may be really educated and not merely informed. As to the depth possible, that will vary with individual powers, and the standard must not be made impossible for the average man; but to give the average man a training in some highly specialised practical department, and then turn him out on the world as a university graduate, is not what we expect or hope for from the new university. Such students there will be, doubtless, and they may well receive special diplomas each in his own branch, but they should not be graduates.

Some other students there will be, who, in addition to a broad and liberal culture, have the power of going deeply into some one subject, and these should receive degrees with honour;

but both these classes will be exceptional. For the average man a broad training in many subjects, well taught and under the most favourable conditions, is what is wanted, in order to leave him adaptable and efficient in the subsequent uncertain calls of actual life; and such men should constitute the bulk of the pass graduates, and be the backbone of the new scheme.

Annexed to the report is an account of the visit of the committee's deputation to American and Canadian Universities, and the information thus obtained and summarised is of the greatest interest and importance.

A deputation of the Advisory Committee of the University of Birmingham paid a visit to colleges and universities in the United States and Canada at the end of last year, on the suggestion of Mr. Carnegie, who, it is understood, is willing to provide a good round sum for the establishment of an adequate scientific and technical college on this side of the Atlantic. An appendix to the committee's report contains a statement of the condition of affairs which they found in America.

They find that "almost the whole of the students enter on a full four-year course of instruction with a view to graduation. The student on entrance is required either to pass an examination or to present satisfactory evidence that he is qualified to take up the course on which he enters. The entrance examination is not very different, as a rule, from the matriculation examination of the University of London. It is more advanced in mathematics, but probably easier on the literary side."

The working session ranges between thirty-three and thirty-eight weeks; but outside this there are summer excursion classes, and summer workshop classes usually of about one month.

One remarkable difference they find in the system of lecturing. With us, college lectures form a connected course, almost dispensing with the necessity of a text-book, except for supplementing and extending information. It has often seemed to us that such lectures are perfectly right if the student already partially knows the subject; it then systematises and organises and more firmly impresses his knowledge; but if, as too often happens, a student comes to the lecture-room ignorant of the subject, he cannot derive proper benefit from a course of lectures; he cannot discriminate between the essential and the comparatively unessential; he cannot without practice watch experiments and take notes at the same time; he cannot always keep his attention fixed: we have noticed that students who have recently been to a British secondary school, one of the large public schools or indeed any other, cannot as a rule keep their attention long fixed on anything. There are exceptional students, and there are exceptional schools; but as a rule what they chiefly learn in class work at school is a habit of inattention to what is going on, the average procedure in class being too slow for the quicker boys, too rapid for the slower ones, and too dull for all. This habit of inattention, once firmly acquired, remains with them through the first year and sometimes through the second year of their college life, and they are all the time a perfect curse to any who wish to get on, and who are becoming of an age to realise some of the responsibilities and opportunities of life.

For the college lectures in America it would appear that "a large amount of home preparation and work is required. The student is expected to read up in a text-book the subject matter of the lectures beforehand, the lectures in many cases consisting of exposition and experimental illustration of the text-book. Recitation classes are held in connection with each lecture, in which individual students are questioned on the text-book or lectures, or asked to demonstrate on the blackboard before the rest of the class."

Literary studies are not wholly neglected by the students of science, nor is attention to them confined to the needs of the entrance examination. In addition to the requirements of the entrance examination in languages, grammar, and history, a certain amount of time is given by the science students, especially in the first two years, to what appear to be often called "culture subjects," such as literature, composition and rhetoric, history, political economy, French and German.

But the most important and much-to-be-imitated portion of the system adopted in America, is that whereby the credit given for work does not depend solely on a concluding examination, but is made really to represent the aggregate work of the whole session. There is a Paper examination, and that is quite right, for it is eminently desirable that a student should be able to express what he knows accurately and on demand. Quite half the credit ought to be awarded to this faculty, but not all; the remaining half should be awarded for work in class-room and laboratory.

In the States there are no practical examinations as with us. Proficiency in laboratory work is accredited by assigning marks for attendance and for excellence of laboratory and manual work throughout the session. We believe that this system is very successfully in force at such places as the City Guilds Central Technical College at South Kensington, but we have not yet heard of its much to be desired introduction into universities in this country. There is no doubt that it would have the best effect on both student and demonstrator; and it would have the further advantage that the troublesome practical examinations, especially those in the senior stage, when they become rather farcical, could be dispensed with.

Another desirable innovation is thus expressed:—"The right of dismissal at any stage is maintained and used. Any student who shows that he is unable or unwilling to keep up with the work is excluded by the Faculty from the graduation course. He may be allowed to take on special courses, but usually he is dismissed from the institution. The system has been devised to keep, and succeeds in keeping, the students continuously at work, and the result of the process of exclusion in the earlier stages is that nearly the whole of the final classes are successful in graduating."

One of the most important arrangements in America is the large provision made at some of the institutions for post-graduate work. Only a small proportion of students are able to spare time for it, but it is encouraged by affording every facility for study and research to the post-graduate; and graduates from one institution frequently work as post-graduates at another. This system of interchange between universities, which already obtains largely in Germany, is surely to be desired in this country, especially in post-graduate stages, where specialisation naturally and properly sets in.

Over-specialisation in undergraduate stages is, we believe, to be deprecated. A certain amount of general knowledge, both literary and scientific, is needed, and should be acquired by all.

The committee found that in America the proportion of staff to students is much greater than with us; and they further found—what is a matter of great importance—that the subdivision of subjects is, as in Germany, likewise carried much further; so that, for instance, every important branch of engineering has its own professor, with perhaps an assistant professor, and certainly with instructors; and no attempt is made, as with us, to place the whole of a gigantic scientific subject in its higher stages under the control of one man.

We observe that in the fundamental subjects of chemistry and physics the general laboratory arrangements and the scope of teaching appear to be much the same in America as in this country. The laboratories are, however, as a rule more spacious, the equipment in apparatus is on a larger scale, greater facilities are given for research, and the size of the laboratories allows most of the physical apparatus to be kept in position—different rooms being used for different subjects. In the more important laboratories many rooms are provided for original research, which is carried on by the staff and post-graduate students. At Cornell there is a special laboratory for physical chemistry. At several colleges there is a department of applied chemistry, through which all students pass who are graduating in chemistry. This is excellent, and tends to make the knowledge much more real and practical. Chemicals are made, instead of being merely purchased; "the course is short, and generally consists in the production of pure chemicals from commercial articles on a scale in which many kilogrammes are dealt with. The processes are made to resemble, as far as possible, those of manufacturing practice."

In civil engineering we observe that "the work in surveying is very thorough, and includes field work throughout the year, together with a summer course. There is usually an extensive stock of theodolites, levels, and chains, so that each student in the field has his own instrument. During the two last years particular attention is devoted to bridge construction, the student preparing complete drawings and stress sheets in accordance with the practice of the leading railway companies."

Less hostile feeling to academically bred apprentices would be felt in this country if these practical features could be imitated.

In mining engineering, a summer excursion class is sometimes formed to spend some weeks in a mining district, where facilities are given to inspect the actual processes of mining.

Great importance is assigned to engineering-laboratory work, and the whole ground of the engineering lectures is provided for in the equipment of the laboratories. The machines are large in number and in capacity, so that every student performs experiments on an adequate scale. The work is chiefly pursued in the third and fourth years, and occupies from four to six hours weekly. In some laboratories there are full-size locomotives mounted, so that running tests can be made, and special courses are arranged for those who wish to take up the mechanical side of railway practice. Facilities are given by the railroad companies for testing under the conditions of actual running.

The shops gave the impression of being thoroughly practical, and on such a scale that the knowledge acquired there by the student would be of use in his subsequent professional life.

The greater size of the Continent is, perhaps, partially responsible for the following paragraph in the committee's report, although really if education were properly appreciated in this country, our island is large enough for us to follow the example. The paragraph we refer to looks very attractive to those whose work in this country lies in colleges cramped in the middle of great cities. It runs as follows:—

"We were very much struck with the amount of ground occupied by the colleges, each building standing in its own grounds, so that it is well lighted on every side. Usually there is a large entrance hall, a fine staircase, and wide corridors leading to class-rooms and laboratories. The floor space in the laboratories is generally very much greater than with us. The apparatus, instead of being huddled away in dark corners, is set out and classified as if for exhibition, while the machinery occupies a space worthy of its importance."

We observe also that every college possesses departmental libraries and reading-rooms available for the students, in addition to the large central library and reading-room.

The social aspect of university life is not forgotten, and the following glorified edition of a student's union is well worthy of imitation:—

"The University of Pennsylvania at Philadelphia possesses in Houston Hall a fine building given to the University by an old graduate, in memory of his son, who was also a graduate. It is a club-house for the students, any student becoming a member for two dollars per annum. In the building are reading, billiard and smoking rooms, a luncheon-room, a gymnasium, a swimming bath, and rooms for college societies. The hall is entirely and very well managed by the students. It is regarded by the staff as having a most excellent influence on student life."

In concluding this part of the general report of their American visit, the committee make a well-deserved comment, which we will presently quote, for nothing more splendid in the direction of educational endowment has been seen in our times than the magnificent sums which wealthy American citizens are willing to place at the disposal of university authorities. They do, indeed, realise, as we do not, or at least have not yet, the immense, the super-eminent, importance of real education and knowledge, to a country and an empire which has to hold its own against ever-increasing competition, and constantly to make its way in fresh uncivilised regions. The following are the concluding general remarks:—

"We desire to express our admiration alike for the high ideal of scientific education, which is the aim in American universities, and for the enthusiasm in all classes which renders it possible to approach so near that ideal. Everywhere we found evidence that the wealthier citizens realise the importance of university education, and encourage the universities by generous gifts; and everywhere, both by teachers and by students, these gifts are being used for higher learning and research."

---

## *THIRD INTERNATIONAL CONFERENCE ON A CATALOGUE OF SCIENTIFIC LITERATURE, LONDON, JUNE 1900.*

### LIST OF DELEGATES APPOINTED TO ATTEND THE CONFERENCE.

*Austria.*—Prof. E. Weiss (Kaiserliche Akademie der Wissenschaften, Vienna); Prof. Karl Toldt (Universität, Vienna).

*France.*—Prof. G. Darboux (Membre de l'Institut de France); Dr. J. Deniker (Bibliothécaire du Museum d'Histoire Naturelle, Paris); Prof. H. Poincaré (Membre de l'Institut de France).

*Germany.*—Prof. Dr. F. Klein (Geheimer Regierungs-Rath, Universität, Göttingen); Prof. Dr. B. Schwalbe (Direktor, Real-Gymnasium, Berlin); Dr. F. Milkau (Oberbibliothekar, Universität, Berlin).

*Greece.*—Mons. de Metaxas (Chargé d'Affaires for Greece).

*Hungary.*—Dr. August Heller (Bibliothekar, Ungarische Akademie, Buda-Pesth); Dr. Theodore Duka (Hon. Member of the Hungarian Academy of Sciences).

*Italy.*—Prof. Giacomo Ciamician (R. Università, Bologna); Prof. Raffaelo Nasini (R. Università, Padua).

*Japan.*—Prof. Einosuke Yamaguchi (Imperial University of Kioto).

*Mexico.*—Señor Don Francisco del Paso y Troncoso.

*Norway.*—Dr. Jörgen Brunchorst (Secretary, Bergenske Museum).

*Switzerland.*—Dr. Jean Henri Graf (President, Commission de la Bibliothèque Nationale Suisse, Berne); Dr. Jean Bernoulli (Librarian, Bibliothèque Nationale Suisse, Berne).

*United Kingdom.*—Representing the Government: The Right Hon. Sir John E. Gorst, Q.C., M.P., F.R.S. (Vice-President of the Committee of Council on Education). Representing the Royal Society of London: Sir Michael Foster, K.C.B., Sec.R.S.; Prof. Arthur W. Rücker, Sec.R.S.; Prof. H. E. Armstrong, F.R.S.; Sir J. Norman Lockyer, K.C.B., F.R.S.; Dr. Ludwig Mond, F.R.S.; Dr. T. E. Thorpe, For.Sec.R.S.

*Cape Colony.*—Sir David Gill, K.C.B., F.R.S.; Roland Trimen, Esq., F.R.S.

*India.*—Lieut.-General Sir Richard Strachey, G.C.S.I., F.R.S.; Dr. W. T. Blanford, F.R.S.

*Natal.*—Sir Walter Peace, K.C.M.G. (Agent-General for Natal).

*New Zealand.*—The Hon. W. P. Reeves (Agent-General for New Zealand).

*Queensland.*—The Hon. Sir Horace Tozer, K.C.M.G. (Agent-General for Queensland).

### ACTA.

*Opening Meeting, Tuesday, June 12, at the rooms of the Society of Antiquaries, at 10 o'clock.*

(1) Prof. Darboux moved that Sir John E. Gorst be the President of the Conference. The motion having been carried unanimously—

(2) Sir John Gorst took the chair and welcomed the delegates.

(3) On the motion of Sir M. Foster, seconded by Prof. Darboux, it was resolved that Dr. F. Milkau be the secretary for the German language; that Dr. Jean Bernoulli and Dr. J. Deniker be the secretaries for the French language; that Prof. Giacomo Ciamician be the secretary for the Italian language; that Prof. H. E. Armstrong be the secretary for the English language.

(4) That the secretaries, with the help of shorthand reporters, be responsible for the *procès verbal* of the proceedings of the Conference in their respective languages.

(5) Sir Michael Foster read out the names of delegates appointed to attend the Conference.

(6) On the motion of Sir Michael Foster, it was resolved—(i.) That the meeting adjourn at 1 p.m., and meet again at 2.30 p.m.; (ii.) that on Wednesday, the meeting commence at 11 a.m.

(7) On the motion of Sir Michael Foster, seconded by Prof. Rücker, it was resolved that English, French, German and Italian be the official languages of the Conference, but that it shall be open for any delegate to address the Conference in any other language, provided that he supplies for the *procès verbal* of the Conference, a written translation of his remarks into one or other of the official languages.

(8) Sir Michael Foster presented the Report of the Provisional International Committee, and it was resolved that the report be received.

(9) The following resolutions were then agreed to:—(i.) That the publication of a card catalogue be postponed for the present; (ii.) that the book catalogue be at first issued only in the form of annual volumes.

(10) Sir Michael Foster having moved (iii.) that the catalogue include both an authors' and a subject index, according to the scheme of the Provisional International Committee; Prof. Rücker thereupon explained the financial position, and the delegates of the various countries stated to what extent they were authorised to promise contributions towards the expenses of the catalogue. From these statements it appeared that subscriptions to 163 sets of volumes (or their equivalent) of the

catalogue, to the value of £2,771, would be guaranteed, viz. as follows :—

| | | | £ |
|---|---|---|---|
| Germany ... ... ... | 45 | sets equivalent to | 765 |
| United Kingdom ... ... | 45 | ,, ,, | ,, 765 |
| France ... ... ... | 35 | ,, ,, | ,, 595 |
| Italy ... ... ... | 27 | ,, ,, | ,, 459 |
| Switzerland ... .. | 6 | ,, ,, | ,, 102 |
| Norway ... ... ... | 5 | ,, ,, | ,, 85 |

Other delegates estimated that the probable contributions from their countries would be :—

| | | | £ |
|---|---|---|---|
| Austria ... ... ... | 16 | sets equivalent to | 272 |
| Hungary ... ... ... | 4 | ,, ,, | ,, 68 |
| Japan ... ... ... | 5 | ,, ,, | ,, 85 |
| Mexico ... ... ... | 5 | ,, ,, | ,, 85 |

It was further estimated that the British Colonies and Dependencies would subscribe for at least 25 sets, equivalent to 425*l*. Taking into account the subscriptions to be expected from the United States, Russia, Holland, Sweden, and a number of other countries, as well as the probability of outside sales, the Conference was of opinion that the necessary subscriptions to cover the cost of 300 sets of the catalogue would be obtained. At the close of the discussion the motion above set forth was unanimously agreed to.

(11) In the course of the discussion, it was stated by delegates from several countries that all the sets subscribed for would be distributed among public institutions, and that they contemplated the private sale of the catalogue in addition.

### *Second Meeting, Wednesday, June* 13.

(12) The following motions, of which notice had been given on the previous day, were considered and adopted :—

(A.) The Conference is of opinion that the financial prospects of the enterprise are sufficiently satisfactory to warrant further steps being taken toward the publication of the catalogue, in view of the fact that the representatives of the various countries have declared that the governments or corporations they represent are willing to subscribe for the number of complete sets of copies at the cost stated in paragraph 10.

La Conférence décide : que le côté financier de l'entreprise est suffisamment élucidé pour justifier les arrangements ultérieurs nécessaires pour la publication du Catalogue, les représentants des différents pays ayant en effet déclaré que les gouvernements ou les corps savants qu'ils représentent sont prêts à souscrire au nombre de séries complètes du Catalogue, et aux prix indiqués dans le § 10.

Angesichts der von den Vertretern der verschiedenen Länder abgegebenen Erklärung, dass die durch sie vertretenen Länder oder Körperschaften entschlossen sind, auf die in § 10 angegebene Zahl vollständiger Exemplare zu dem ebenda festgesetzten Preise zu subskribiren, gibt die Konferenz der Meinung Ausdruck, dass die finanziellen Aussichten des Unternehmens zufriedenstellend genug sind, um weitere Schritte zur Veröffentlichung des Katalogs zu rechtfertigen.

La Conferenza è d'avviso che avendo i rappresentanti dei diversi paesi dichiarato che i governi o i corpi scientifici da loro rappresentati sono pronti a sottoscrivere nella misura indicata al § 10, si può ritenere l'impresa abbastanza soddisfacente dal lato finanziario per autorizzare gli ulteriori passi che sono necessari per la pubblicazione del catalogo.

(B.) That, pending the appointment of the International Council, a Provisional International Committee be appointed which shall be entrusted with the duty of approaching, through the Royal Society, such countries as may be necessary, with the view of obtaining their adhesion to the scheme for the publication of the catalogue, or promises of financial support.

Que jusqu'à la constitution définitive du Conseil International, un comité international provisoire soit nommé. Ce comité sera chargé de se mettre en rapport par l'intermédiaire de la Société Royale, avec les personnes autorisées des différents pays, suivant les nécessités de la situation, afin d'obtenir de ces pays l'adhésion ou l'appui financier à l'œuvre du Catalogue.

Dass bis zur Einsetzung des *International Council* ein *Provisional International Committee* ernannt wird, mit dem Auftrage, sich durch die Vermittelung der Royal Society mit den in Betracht kommenden Ländern in Verbindung zu setzen, um sich ihrer Mitwirkung bei der Veröffentlichung des Katalogs zu versichern oder ihre Zusagen für finanzielle Unterstützung zu erwirken.

Che sia nominato un comitato internazionale provvisorio sinò a che non sarà costituito definitivamente il Consiglio Internazionale. Questo comitato avrà l'incarico di mettersi in comunicazione mediante la Royal Society con i diversi paesi, secondo che sarà necessario, per ottenere la loro adesione al progetto di pubblicazione del catalogo o la promessa del loro appoggio finanziario.

(C.) The said Provincial Committee is further authorised to make other preparations for the publication of the catalogue, but without incurring financial responsibility.

Inasmuch as it will be necessary for some one corporation to make the necessary contracts and undertake the final financial responsibilities, the Provincial Committee is authorised to include among such preparations, negotiations either with the Royal Society, or with another corporation, or with a government, or with a publisher, but the confirmation of all such preparations, and the carrying out of any final agreement or contract, shall rest with the International Council.

Ce comité sera autorisé en plus à prendre d'autres mesures préliminaires en vue de la publication du Catalogue ; mais il n'aura aucune responsabilité financière.

Comme il sera nécessaire, pour un corps constitué quelconque, de conclure des traités et d'encourir les responsabilités financières définitives, le comité provisoire est autorisé à comprendre parmi les mesures préparatoires de ce genre, les négociations soit avec la Société Royale, soit avec un autre corps constitué, soit avec un gouvernement, soit avec un éditeur. Toutefois la confirmation de toutes ces mesures préparatoires, ainsi que l'arrangement financier définitif ou conclusion d'un traité, doivent incomber au Conseil International.

Das genannte Provisional Committee wird ferner beauftragt, andere Vorbereitungen zur Veröffentlichung des Katalogs zu treffen, ohne jedoch eine finanzielle Verantwortlichkeit einzugehen.

Soweit es notwendig ist, dass eine Korporation die erforderlichen Verträge abschliesst und die endgültige finanzielle Verantwortlichkeit übernimmt, wird das Provisional Committee ermächtigt, derartige Vereinbarungen entweder mit der Royal Society oder mit einer anderen Korporation oder mit einer Regierung oder mit einem Verleger einzuleiten, indem die Bestätigung solcher Verhandlungen wie die Ausführung der endgültigen Vereinbarungen dem International Council vorbehalten bleibt.

Questo comitato sarà inoltre autorizzato a prendere altre misure preliminari per la pubblicazione del catalogo, senza avere tuttavia nessuna responsabilità finanziaria.

E poichè è necessario per un corpo costituito di concludere dei contratti e d'assumere la responsabilità finanziarie definitive, così il comitato provvisorio è autorizzato ad includere nei lavori preparatori le trattative o colla Royal Society o con altre corporazioni o con un governo o con un editore : ma la conferma di queste trattative e l'approvazione finale del contratto sarà riservata al Consiglio Internazionale.

(13) The "Scheme for the Publication of an International Catalogue of Scientific Literature" was then considered, and it was resolved—

That Article I. be approved—

Omitting the words in paragraph 5 on page 5, lines 9 and 10, "the limits of the several sciences to be determined hereafter," and also the words, page 5, lines 27–29.

That Article II. be approved—

Omitting the words "the same . . . regulations were" in paragraph 10, page 7 ;

Adding Italian to the three languages mentioned in paragraphs 10 (*a*) and (*b*) ;

Altering the word "delegate" to "contracting body (as hereinafter defined)" in paragraph 10 (*d*) ;

Omitting at the top of p. 8 the words within square brackets ;

Omitting in paragraph 11, p. 8, the words within square brackets : "The . . . Appendix II.," and substituting the following : "Each contracting body shall have one vote in deciding all questions brought before the Council" ;

And inserting in paragraph 13, before the words : "There shall also be . . ." the words : "If the International Council so decide."

That Article III. be approved without change.

That Article IV. be approved, omitting the opening paragraph in square brackets.

That Article V. be approved, inserting the words: "or as soon after that date as the International Council may decide," in paragraph 29, after "January 1, 1901."

That Article VI. be approved, inserting at the beginning of paragraph 32, the words: "Unless the International Council decide otherwise";

Substituting in paragraph 34, p. 14, line 33, "instructed" for "authorised."

That Article VII., excepting paragraph 37, be approved—

Omitting paragraph 35 and the next paragraph in square brackets, and substituting therefor: "any body which establishes a regional bureau shall be termed a contracting body."

Omitting the words "which takes a complete share" in the first line of paragraph 40, and omitting the whole of the second sentence in this paragraph, and omitting the three appendices.

(14) It was further resolved to substitute for paragraph 37, Section VII., page 15, the following:—

"That it will be an instruction to the Provisional Committee to negotiate with the several contracting bodies with reference to the sale in their respective regions of copies other than those subscribed for by the contracting bodies."

Que les instructions soient données au comité provisoire pour négocier avec les différents corps contractants la question de la vente dans leurs pays respectifs des exemplaires souscrits par ces corps.

Aufgabe der Provisional Committee wird es sein, den verschiedenen contrahierenden Körperschaften (contracting bodies) bezüglich des Verkaufs von Exemplaren in ihren Ländern, ganz abgesehen von der gewahrleisteten Anzahl, bestimmt e Festsetzungen vorzuschlagen.

(15) It was resolved that the Provisional Committee contemplated in Resolution 12 (B) be constituted as follows:—Prof. Armstrong, Dr. Brunchorst, Dr. Graf, Dr. Milkau, Prof. Nasini, Prof. Poincaré, Prof. Weiss; power being given to the Royal Society, while retaining only a single vote, to nominate further members, and power being given to the Committee to appoint substitutes if any of those named were unable to serve, and also to co-opt two new members.

(16) On the motion of Sir Michael Foster and Prof. Rücker, it was resolved that the Royal Society be requested to appoint the Secretary to the Provisional Committee, and to meet provisionally such expenses as the Committee may incur.

(17) It was resolved that the *procès verbal* of the Conference be signed by the president and secretaries.

(18) The Royal Society was requested to undertake the editing, publication, and distribution of a verbatim report of the proceedings of the Conference.

(19) On the motion of Prof. Schwalbe, a vote of thanks to Sir John Gorst for presiding over the Conference was passed by acclamation.

(20) On the motion of Sir Michael Foster, the thanks of the Conference were accorded to the Society of Antiquaries for the use of their rooms.

(Signed) JOHN E. GORST.
HENRY E. ARMSTRONG.
DR. JOH. BERNOULLI.
G. CIAMICIAN.
J. DENIKER.

## THE ROYAL SOCIETY CONVERSAZIONE.

THE exhibitions at the conversazione, which took place on the 20th inst., were numerous and interesting. There was a great wealth of photographs, including a large collection illustrating the results obtained during the last total eclipse. Among the other objects exhibited were the following:—

Prof. W. Ramsay, F.R.S., and Dr. M. W. Travers exhibited the inert atmospheric gases; their spectra, and some of the apparatus used in determining their physical properties.

The Meteorological Office exhibited North Atlantic weather charts, winter, 1898-99.

Prof. J. W. Judd, C.B., F.R.S., on behalf of the Coral-Reef Committee of the Royal Society, exhibited specimens from the reefs of Funafuti.

Mr. J. Mackenzie Davidson exhibited a stereoscopic fluoroscope. The stereoscopic fluoroscope is an instrument to enable an observer to see the shadows cast by the Röntgen rays on the fluorescent screen in *stereoscopic relief.*

Prof. W. E. Dalby exhibited a model to illustrate and experiment upon the balancing of four-cylindered engines.

Prof. Silvanus P. Thompson, F.R.S., showed experiments on the aberration called *Coma*. Coma is an aberration due to the several zones of the lens not having equal focal lengths, and hence, when the lens is transmitting an oblique pencil, the unequal refraction of the different parts gives rise to a singular unilateral distortion of the cones of rays traversing the various zones. In these experiments, the effects are analysed by covering the lens with a series of zones alternately opaque and transparent. Some singular effects can also be produced without the zone plate, by inserting in the oblique pencil, after traversing the lens, objects to cast shadows on a screen. In this way a straight wire can be arranged so that the shadow it casts is a totally-detached circle. Some diagrams of coma, and a string model illustrating their origin, were also shown.

Mr. W. Gowland exhibited Japanese books on botany, intended to show the general character of the work of Japanese botanists from 1759 to 1856.

Mr. W. Gowland, for the Silchester Excavation Committee, exhibited remains of a Roman silver refinery found at Silchester.

Mr. S. Evershed exhibited an electric supply meter (a frictionless motor meter).

Prof. H. S. Hele-Shaw, F.R.S., and Mr. A. Hay showed lines of induction in a magnetic field, represented by stream-line flow.

Prof. E. Ray Lankester, F.R.S., exhibited enlarged models of gnats (mosquitoes) and of human blood-corpuscles infected by the malaria-parasite; modelled by Miss Delta Emett. (1) Female *Culex pipiens*, Linn., the common brown gnat or mosquito; enlarged twenty-eight times linear. The insect is shown in the act of alighting. This gnat does not harbour the malaria-parasite. (2) Female *Anopheles maculipennis*, Hoffmansegg, the common spot-winged gnat or mosquito; enlarged twenty-eight times linear. (3) Models of human blood-corpuscles infested with the malaria-parasite (æstivo-autumnal or remittent fever) known as *Haemomenas praecox*; magnified seven thousand five hundred times linear. The blood-corpuscles are transparent, and show the parasites within. The upper row shows the multiplication of the parasite within the corpuscles by fission giving rise to "sporocytes," which creep into other non-infected blood-corpuscles and repeat the process, thus increasing the infection. The lower row shows the formation of a crescent-shaped "gametocyte" within the blood-corpuscle. Instead of breaking up, the parasite enlarges and becomes sausage-shaped. The "gametocytes" thus formed are destined to be swallowed by the gnat Anopheles, when they develop in the gnat's stomach —some into eggs and some into spermatozoa.

The Zoological Society of London showed two living female crowned lemurs (*Lemur coronatus*), each with a young one.

Prof. G. B. Howes, F.R.S., and Mr. H. H. Swinnerton exhibited reconstructional models, built up from microscopic sections, of the developing head skeleton of the New Zealand reptile, *Sphenodon punctatus.*

Sir John Evans, K.C.B., F.R.S., exhibited ancient cameos and gems, and palæolithic implements from Africa.

Prof. Wyndham Dunstan, F.R.S., exhibited the poisonous lotus of Egypt (*Lotus Arabicus*). (*a*) Living plant grown at Kew. (*b*) Dried plants from Nubia. (*c*) Specimens of the new glucoside, *Lotusine*, and its decomposition products.

Mr. Fred Enock exhibited an aquatic walking-stick insect, with eggs (*Ranatra linearis*).

The following demonstrations, with experiments and lantern illustrations, took place:—

Mr. Fred Enock, life-history of the *Cicindela campestris*—the common tiger beetle. This common Coleopteron goes through its metamorphoses in deep vertical burrows made in the sand by the curious larva, which "sits" at the top of the hole, patiently waiting for its prey to come to it, as it does not go in search of it. Three years are passed in its subterranean den, at the lower end of which it remains during the winter months in a semi-torpid state; activity is resumed at the approach of warm weather.

Prof. J. A. Fleming, D.Sc., F.R.S., demonstrations with an apparatus for the production of short electric waves, and the study of electro-optic phenomena. The apparatus exhibited consists of a radiator for the production of a beam of electric radiation, the wave-length being about eight inches. The radiator is contained in a zinc box, which prevents the diffusion of the radiation in all directions. The receiver consists of a metallic filings tube of the Branly type, associated with a relay and electric bell. The receiver is also contained in a zinc shielding box. The impact of electric waves upon the receiver is indicated by the ringing of the bell. The radiator can be placed at different angular positions. With this apparatus are shown experiments illustrating the opacity of metallic screens, continuous or perforated to electric radiation; the transparency of insulating screens, and the transparency or opacity of various liquids. Water is found to be particularly opaque even in very thin layers. All damp objects are very impervious to this radiation, such as a wet duster, a moist brick, tobacco having more than the legal amount of water added to it, and the human body or hand. The refraction of electric waves is shown by the use of a paraffin wax prism, the concentration by paraffin lenses, and the polarised quality of the rays by their reflection or stoppage by parallel wire gratings. Also the production of secondary oscillations in linear conductors by holding rods of metal or tubes of liquid in the radiation. The wave-length of the radiation is measured by producing interference as a result of splitting the beam into two portions and transmitting the two portions down two zinc tubes, the relative lengths of which can be adjusted.

Prof. A. C. Haddon, F.R.S., cinematograph photographs of native dances in Torres Straits.

## *THE RE-ORGANISATION OF THE EDUCATION DEPARTMENT.*

IN introducing the Secondary Education Bill to the House of Lords on Tuesday last, the Duke of Devonshire made the following remarks on the re-organisation of the Education Department:—

"Your lordships may remember that on the Bill of last year some discussion took place upon the future organisation of the Education Department. I thought at the time, and I am still more strongly of opinion now, that that discussion was somewhat premature. It proceeded on the assumption that the organisation of the new office would continue on the same lines as those which had existed when the educational departments were separate and distinct, and that there would be in the new office two divisions, one of which would carry on the work of the old Education Office in connection with elementary education, and the other of which would carry on the work of the Science and Art Department. . . . We now propose to revert to a dual organisation of the office, but not entirely upon the lines of the late Education and Science and Art Departments. The principal officers of the department which we propose will be a principal permanent secretary, who will supervise generally the whole work of the department. It must be remembered, when special importance is attached to this or that minor subordinate appointment, that it will be the permanent secretary who will be responsible to the President of the Board in the administration of the whole department, and that it is impossible, and would be undesirable if it were possible, that the office should be divided into what I may call water-tight compartments, the head of each of which would be charged with special duties and no other, and that the idea should be entertained that the work of the office should be carried on in several departments, which should have no connection or relation with each other. We propose that under the principal permanent secretary there shall be two principal assistant secretaries, one mainly charged with duties in connection with elementary and the other with secondary education. We propose to abolish the name 'Science and Art Department.' The Science and Art Department will be merged in the secondary education branch of the office. As soon as it may be possible, we propose to transfer the greater part of the staff of the late Science and Art Department from South Kensington to Whitehall, except such part of it as may be necessary to leave at South Kensington for the administration of the museum and the colleges of science and art. In place of the third division that was contemplated, we now propose to give the principal assistant secretary of secondary education two additional assistant secretaries, one of whom will be chiefly charged with the supervision and control of literary instruction, and the other of technological study. This is not the organisation, I admit, to which I partly committed myself last year; but I trust that it may, in substance, meet the views, especially the later views, which have been expressed to me by high educational authorities. With the name we hope to get rid of many of the traditions which were supposed to attach to the old Science and Art Department—traditions which have, I believe, been regarded as opposed to the true interests of education by many of those who have been responsible for the management of the older endowed schools. The original idea of the Science and Art Department was, or at all events was supposed to be, that by means of lectures, classes, and examinations a knowledge of the principles of science and art, which would be valuable to the students themselves and to the nation at large, could be engrafted upon almost any kind of previous elementary or secondary training. It is quite true that this idea has been in recent years very largely modified, but I do not think that it is yet generally known how far the original traditions of the Science and Art Department have been already departed from. We hope and intend that the idea of the future education branch of the office will be to make science and art instruction a part of general education in addition to those classical and literary studies which have hitherto formed its main portion. In the schools and institutions directly assisted by the Board of Education the teaching of science and of art, with the addition, perhaps, of some commercial subjects, will probably remain the principal object. But, on the other hand, in those secondary schools, whether of older or more modern type, which desire to enter into connection with the board, there ought not to be, and there need not be, any interference with the older classical and literary studies so long as there continues to be a demand for them. At the same time, we hope that the scientific resources of the Board will be placed at their disposal if they desire, as many of them do desire, to develop the more modern sides of instruction and education. . . . It may be of interest to the House to know what are the principal appointments which have been made or are proposed to be made in the principal office of the new secondary education branch of the department. Sir George Kekewich, the late secretary of the Board of Education, has become the permanent principal secretary of the new Board, and it is he who will be responsible to the President of the Board and to the Government for the administration of the department as a whole. The principal assistant secretary for secondary education will be Sir William Abney, who has done more than any other man in extending the studies of the schools of science under the Science and Art Department. Under him the assistant secretary to deal with the literary side of instruction will be Mr. Bruce, an assistant commissioner to the Charity Commission under the Endowed Schools Act, who has been chiefly engaged and has obtained much experience in the administration of the Welsh Act. The assistant secretary for technological study has not yet been appointed."

## *UNIVERSITY AND EDUCATIONAL INTELLIGENCE.*

CAMBRIDGE.—Prof. Sir Michael Foster has been nominated by the Council of the Senate as the representative of the University of Cambridge on the Council of the Jenner Institute of Preventive Medicine.

Mr. A. W. Hill, of King's College, and Mr. L. Lewton-Brain, of St. John's College, have been appointed University Demonstrators in Botany.

Mr. E. E. Walker, Trinity College, has been elected to the Harkness Scholarship in Geology and Palæontology.

Prof. Woodhead announces ten courses of lectures and demonstrations in Pathology and Bacteriology to be held during the ensuing Long Vacation.

Mr. Shelford Bidwell, F.R.S., was on June 19 admitted to the degree of Doctor of Science.

Mr. W. N. Shaw, F.R.S., has been elected a Senior Fellow of Emmanuel College. It is a condition attaching to his tenure that he shall give annually in the University not less than three lectures on the Physics of the Atmosphere or some kindred subject. Mr. C. T. R. Wilson, F.R.S., formerly Clerk Maxwell Student in experimental physics, has been elected to a fellowship at Sidney Sussex College.

The following have been awarded scholarships or exhibitions in Natural Science at the several colleges at the end of the academical year:—

Clare College: Bailey, Cartwright, Cassidy, Hughes.

Pembroke College: Lang, Anderson, Hall.

King's College: Kewley, French, Wilde, Mollison, McIntyre.

Christ's College: Fox, Moore, Wilson, Macnab, Muff, Cumberlidge, Sewell.

Emmanuel College: Nixon, Austin, Sutton, Rothera, Banham.

Sidney Sussex College: Bullough, Colt, Drapes, Fearnsides, Harrison, Humphrey, Robinson, Gough.

THE *Appointments Gazette*, which is the journal of the Cambridge Appointments Association, gives in its last issue (June 1900) much valuable information regarding scientific and other posts open to university graduates. It also contains articles on post graduate work in medicine, by Prof. Allbutt; on training for business, by Mr. G. E. Foster; and on Long Vacation courses in French, by Mr. H. J. Millar. A list of some two hundred graduates seeking appointments in various departments of industry, with their university qualifications, ages, &c., completes the journal. This list might be consulted with advantage by heads of departments and others in search of suitable candidates for vacant appointments. The Association is doing a useful work in bringing together employers and employed in the various walks of life where university training is of importance, and it already possesses a large and influential membership. The Master of Trinity is chairman, Mr. W. N. Shaw, F.R.S., vice-chairman, and Mr. W. A. J. Archbold, secretary.

PROF. OLIVER J. LODGE, F.R.S., has been appointed Principal of the University of Birmingham.

THE following appointments at the University College of North Wales, Bangor, are announced:—Mr. W. W. Firth to be assistant lecturer in Electrical Engineering, and Mr. Alexander Darroch to be assistant lecturer in the Day Training Department. Mr. W. Cadwaladr Davies was appointed the representative of the Council upon the Central Welsh Board, and Mr. H. Bulkeley Price the representative on the Carnarvonshire County Governing Body.

DR. JOHN WILLIAM WHITE, of Philadelphia, has been elected to the John Rhea Barton Chair of Surgery in the University of Pennsylvania; Dr. Frank Morley, of Haverford College, has been appointed professor of mathematics in Johns Hopkins University, vice Prof. Thomas Craig, resigned; Prof. Charles J. Bartlett takes the place of Prof. M. C. White, who for thirty-three years has filled the chair of pathology in the Medical School of Yale University.

THE Report of the Council to the Governors of the City and Guilds of London Institute, dated March 1900, has just been issued, and gives a full account of the work accomplished in connection with the year 1899, and contains verbatim reports of the addresses delivered respectively by Sir Andrew Noble and Sir Douglas Fox at the opening of the session, and at the distribution of certificates and prizes. We notice from the report that during the past twenty years the work of the Examinations Department has developed to an enormous extent: thus in 1888 the number of subjects of examination was 24, the number of centres of examination 89, and the number of candidates 816. In 1899 the number of subjects had increased to 63, the number of centres to 397, and the number of candidates to 14,004; the number of registered classes being 1764, and of students in attendance 34,176. These numbers are exclusive of those who receive instruction in manual training. The total number of students last year in the classes registered by the Institute was 36,155, as compared with 34,990 in the previous year.

THE following gifts and bequests for scientific and educational purposes are noticed in *Science*:—By the will of the late Jonas G. Clark, of Worcester, Mass., who founded Clark University in 1889, the entire estate is left to the University, providing the people of Worcester raise a fund of 500,000 dollars. If the sum of 250,000 dollars is raised, he bequeaths 500,000 dollars. If 500,000 dollars is raised, he bequeaths 1,000,000 dollars and makes the University his residuary legatee. He also leaves 100,000 dollars for the University library and a similar sum for a department of art. Messrs. Samuel Cupples and Robert S. Brookings have each given to Washington University one-half of the total capital stock of the St. Louis Terminal Cupples Station and Property Company, which company owns the so-called "Cupples Station." The annual income from this gift to the University will be from 120,000 to 130,000 dollars per year. The gift is to form a permanent endowment fund, the interest of which is to be expended by the Board of Directors in any way which it sees fit. Dr. D. K. Pearsons has offered 50,000 dollars to Carleton College, Northfield, Minn., on condition that the college authorities raise 100,000 dollars before January 1, 1901. By the will of Henry M. Curry the Western University of Pennsylvania receives 10,000 dollars for scholarships; and the University of Pennsylvania has received 20,000 dollars from Mr. J. D. Lippencott and Mr. J. G. Carruth respectively.

THE second general meeting of the Agricultural Education Committee was held on Friday last at the rooms of the Society of Arts. The report of the executive to the general committee gave a brief account of the constitution and proceedings of the committee from its commencement, and explained that its objects were: (1) to secure systematic and efficient instruction, both theoretical and practical, in agricultural subjects suitable to every class engaged in agriculture; and (2) to diffuse among the agricultural classes a more thorough appreciation of the advantages of instruction bearing directly or indirectly on their industry. The policy of the committee, the report stated, was largely recognised in the new Day School Code; and the block grant, the continuous course of rural instruction, lessons in "common things" given through the standards, and the new subject of household management for girls, were all on the lines of the committee's resolutions. Moreover, the executive believed that it was largely due to the representations of the committee that the new Board of Education, shortly after its formation, issued a circular to managers and teachers of rural elementary schools impressing on them the importance of making education in the village school more consonant with the environment of the scholars than was now usually the case, and especially encouraging the children to gain an intelligent knowledge of the common things which surround them in the country. Other provisions of the new Code were referred to with satisfaction, and the report stated that the committee had not failed to co-operate with the Board of Education in bringing them into effect. With regard to the work which remained to be done, attention should be given to organisation. It would seem that the precedent successfully set some years ago in Scotland of handing over the educational work of the Board of Agriculture to an educational authority, while leaving to the Board the inspection of experimental and research work, might well be followed. If that was not done, and the present division of functions continued, the cause of rural education, especially in its higher branches, would undoubtedly suffer. It was also to be hoped that attention would be given to the training of teachers, and that the new Board would introduce some modifications into the curricula of the training colleges to ensure the qualification of a certain number of trained teachers to give instruction on elementary science and common things required by the Code. A good deal also remained to be done in placing evening continuation work on a satisfactory footing.

## SCIENTIFIC SERIALS.

*American Journal of Science*, June.—A method of studying the diffusion (transpiration) of air through water, and a method of barometry, by C. Barus. The diffusion of air through water is studied by observing the gradual loss of the air contained in a Cartesian diver, and this loss is determined from the change in the temperature coefficient contained in the equation of flotation. The same equation also involves in a simple manner the height of the barometer; and a Cartesian diver apparatus is, therefore, virtually a water barometer which need only be one foot high instead of thirty feet.—Separation and determination of mercury as mercurous oxalate, by C. A. Peters. The author estimates mercurous salts volumetrically by precipitating with ammonium oxalate, and determining the oxalic acid by potassium permanganate, and gravimetrically by direct weighing of the precipitate.—Electrical resistance of thin films deposited by kathode discharge, by A. C. Longden. The thinnest films have a resistance which is very much higher than is warranted by their thinness. The sign of the temperature coefficient of resistance varies with the thickness, and it is therefore possible to obtain resistances by kathode-ray deposition which do not vary with the temperature. Such resistances form valuable high-resistance standards.—New meteorite from Oakley, Logan county, Kansas, by H. L. Preston. This is a siderite of 61 lbs. found in 1895.—Some observations on certain well-marked stages in the evolution of the Testudinate humerus, by G. R. Wieland. The development of the humerus of the turtle presents a special interest on account of its graduated change of habitat from dry deserts to the ocean.—Geothermal gradient in Michigan, by A. C. Lane. The geothermal gradient at Bay City is 1·5 degrees F. per 100 feet. The Upper Peninsula is a region notorious for its much lower gradient. The author discusses the various hypothesis framed to account for the differences in the gradient. Among these are the cooling action of Lake Superior, a survival of the Ice Age coldness, and differences in the conductivity of rocks. The author favours the last hypothesis.—Production of X rays by a battery current, by J. Trowbridge. The installation of a plant of 20,000 storage cells at the Jefferson Physical Laboratory has enabled the author to obtain X-rays of exceptional brilliancy, yielding negatives of great contrast. When the X-ray tube is first connected with the battery terminals no current flows. It is necessary to heat the tube, when it suddenly lights up. A distilled-water resistance of about 4,000,000 ohms is inserted in the circuit.

*Annalen der Physik*, No. 5.—Change of conductivity of gases by a continuous electric current, by J. Stark. The resistance of a gas conveying an electric current is highest near the electrodes, owing to the accumulation of ions of the same sign in this neighbourhood. It has another maximum near the middle, but rather more towards the side of the anode. The resistance is influenced by the heat developed at the electrodes, by the kathode rays, and by the unequal speed at which the two kinds of ions travel through the gas.—Objective presentation of the properties of polarised light, by N. Umow. A beam of parallel plane-polarised light is allowed to fall on various geometrical bodies whose surfaces have peculiar optical properties, such as a cone covered with fuchsine, a quartz plate, or a Babinet compensator. The reflection or transmission of the light gives rise to striking colour phenomena. Peculiar spiral effects are obtained by sending the beam through an opalescent colophonium emulsion.—Magnetic screening, by H. du Bois and A. P. Wills. In this portion of their work, the authors calculate and verify the effect of a triple screen of iron for galvanometers. The external diameters of the three screens are 2·5, 4·3 and 8·0 cm. respectively, and their thicknesses are 0·27, 0·18 and 0·18 cm. The total theoretical "screening ratio," *i.e.* the ratio by which the disturbing magnetic field is reduced, is 60·2, and the observed ratio is 64·6.—Armoured galvanometers, by H. du Bois and H. Rubens. Describes some galvanometers screened in accordance with the results of the previous paper.—Rotating magnetic flag, by G. Jaumann. A small magnet mounted like a flag on a glass rod as an axis may be given a continuous rotation by immersing it in mercury contained in a glass vessel surrounded by a tight-fitting copper vessel, with a current traversing the body of the mercury and returning through the copper vessel. The work spent in overcoming the resistance of the mercury is derived from the current itself. It appears as a counter E.M.F. until the mercury rotates with the magnet.—Thermal deformation of balances, by T. Middel. Delicate balances show a considerable change of sensitiveness with the temperature. The author shows that this is due to the bending of the beam of the balance, owing to the unequal expansion of the upper and the lower portion, and that is due to the unequal working of the metal, the coefficient of expansion for cast brass being less than that of rolled brass.—The additive character of atomic heats, by S. Meyer. The author shows that in the case of twenty-six oxides an excess of the sum of atomic volumes over the molecular volume is accompanied by an excess of the aggregate atomic heats over the molecular heat, and that a defect of atomic volumes is accompanied by a defect of atomic heats in the same manner. Boron and bismuth sesquioxides are the only exceptions.

*Bulletin de l'Académie des Sciences de St. Pétersbourg*, vol. viii. No. 1.—Yearly report of the Academy.—A newly-discovered Old Turkish inscription, by Dr. W. Radloff, preliminary report. The inscription was discovered by Madame Elizabeth Clements near Urga, and excellent reproductions of it were made. Dr. Radloff found that it was made in honour of the wise Toyukuk, father-in-law of Bilga-khagan, who was born in 646 of our era.—On the elements of earth-magnetism at Kamenets, Khotin and Odessa, by W. Dubinsky.

Vol. viii. No. 2.—On the rapid motion of the line of the absides in the system of $\alpha'$ Gimini, by A. Byelopolsky.—On the spectroscopic determination of the movements of $\gamma$ Virginis, by the same.—Aurora borealis observed at Pavlovsk on December 20, 1897, by V. Kuznetsoff, with two photographs.—Hydrobiological researches at the Sebastopol Biological Station, by A. Ostroumoff.

Vol. viii. No. 3.—On the attempts at reproducing cometary phenomena by means of experiments, by Th. Bredikhin (in Russian). The recent results obtained by photography permitted us to obtain most exact reproductions of cometary forms. They stimulated the desire of producing theories of comets, and, as far as the author knows, five different theories were proposed lately; they differ essentially in their fundamental principles. No great comets having appeared lately, the earlier drawings, made by previous astronomers, necessarily must be taken into account. Bredikhin found it necessary, therefore, to systematically discuss the facts which relate to the variety of forms of comets, and the passages from the one form to another. These facts can be ignored by no theory, and the author consequently analyses those criteria which must be applied to each theory of the comets.—On the way of building magnetic observatories, by H. Wild.—Description of a very rare case of *Craniopagus parietalis*, by J. Ziematzky (plate).—On the influence of the terms of third order in the perturbations function of the movement of the earth round its centre of gravity on the formulæ of nutation, by A. Ivanof (in French). The author gives a new formula for reducing the length of the second pendulum for any geocentric latitude.

Vol. viii. No. 4.—Ephemerid of the comet of Encke from June 1 to July 31, 1898, by A. Ivanoff.—On the differences of the horizontal intensities of earth magnetism obtained from observations of the unifilar and the bifilar theodolite, by H. Wild.—Positions of 1041 stars of the star-cluster 5 Messier, deduced from photographs, by Madame Shilow. Full list, compiled from careful measurements made on photographic plates.

## SOCIETIES AND ACADEMIES.

### LONDON.

**Royal Society**, May 31.—"The Crystalline Structure of Metals." Second Paper. By Prof. J. A. Ewing, F.R.S., and Walter Rosenhain, B.A.

The investigations described in this paper deal principally with the phenomena of annealing. The first section of the paper describes experiments made in the hope of observing under the microscope the process of recrystallisation in strained iron. This attempt to watch the process of recrystallisation failed, although the experimental difficulties of keeping a specimen under microscopic observation while it was being heated were successfully overcome. The specimen was electrically heated in a vessel with a thin glass or mica window, and the microscope-objective was kept cool by directing a strong blast of cold air on it and on the surface of the window.

The next section of the paper deals with the changes of crystalline structure which go on in lead and other metals at comparatively low temperatures. The authors' attention was directed to this by noticing that a piece of plumber's sheet lead, when etched with dilute nitric acid, exhibits a strikingly crystalline structure, with large crystals. The character of this appearance led the authors to the view that a slow process of annealing or recrystallisation was at work in such lead at ordinary atmospheric temperatures, and the authors have satisfied themselves that this is the case. The method of investigation consisted in taking a series of micro-photographs, at low magnifications, of certain marked areas in the surface of a specimen, in order to watch the change which went on through lapse of time, or after application of some thermal treatment.

When a piece of cast lead is severely strained by compression, the originally large crystals, after being considerably flattened, are driven into and through one another, so that the etched surface of a strained specimen presents a fine grain, whose crystalline nature only becomes apparent under considerable magnification (80 to 100 diameters). A piece of lead severely strained in this way, and kept for nearly six months in an ordinary room without any special thermal treatment, was found to be undergoing continuous change during that time. A series of photographs of this specimen, taken at intervals during the six months, show that a great number of the small crystals have grown larger at the expense of their neighbours. In similar specimens which have been kept at 200° C., the growth has been much more rapid and more pronounced. The rate of growth is a function of time and temperature, but some specimens show much more rapid changes than others under similar conditions of temperature; in some cases five minutes' exposure to a temperature of 200° C. is sufficient to alter the crystalline pattern completely. Experiments have also been made at 100° C. and 150° C., leading to the general result that crystalline growth will occur at any temperature from that of an ordinary room, *i.e.* 15° C. or 20° C., up to the melting point of lead, and that in general the higher the temperature the more rapid is the initial rate of change. No numerical data can be given, as the crystals are quite irregular, both in size and shape.

A comparison of micro-photographs of the same specimen at various stages reveals the fact that the growth of an individual crystal occurs, not in uniform layers all round it, but by the formation of arms and branches that invade the neighbouring crystals, the intervening portions sometimes changing at a later stage. This action is analogous to the formation of skeleton crystals in a metal during solidification from the liquid state, the space between the branches filling in as solidification proceeds.

A marked feature observed in several specimens was the large and rapid growth of one or two individual crystals; in several instances such individuals grew until they were some hundreds of times larger than their neighbours. Generally the most aggressive crystals were found near the edges of the specimen. It is noticeable that at times a crystal which has already grown considerably is swallowed up by a more powerful neighbour.

Some light is thrown on the nature of these actions by the fact that this growth only occurs in crystals that have been subjected to severe plastic strain. By casting the metal in a chill mould, specimens of lead can be obtained having a crystalline structure quite as minute as that found in a severely strained specimen, but this structure remains unchanged at temperatures which produce rapid change in a strained specimen.

The investigation of the effects of such comparatively moderate temperatures was extended to other metals, viz. tin, zinc and cadmium. In tin, the various phenomena of crystallisation from the fluid state are strikingly illustrated on a large scale by the thin layer of that metal which constitutes the surface of commercial tin-plate. The effects of rapid and slow solidification in producing small or large crystals respectively are well marked, and an examination of the etched surface of tin-plate under the microscope reveals beautiful geometrical markings or pits, whose oriented facets produce the well-known selective effect of oblique illumination. The study of the crystalline structure affords an explanation of the nature and method of production of patterns in "moirée métallique," a process which has long been in use for the decoration of articles manufactured of tin-plate.

The final section of the paper deals with an hypothesis, which is advanced as an attempt to explain the mechanism of the growth of crystals in apparently solid metal.[1] According to this hypothesis, the metallic impurities which are present in a metal play an important part in the action. When a metal solidifies from the fluid state, the metallic impurities ultimately crystallise as a film of eutectic alloy in the inter-crystalline junctions; when fairly large quantities of such eutectics are present, the microscope reveals their presence as an inter-crystalline cement, such as that formed by "pearlite" in slowly cooled mild steel; very minute quantities of eutectic, however, will be invisible and yet capable of forming a thin film of fusible cement. The authors conceive that the changes of crystalline structure which go on while the piece is in the solid state are accomplished by the agency of eutectic films between the crystals, in dissolving metal from the surfaces of some crystals and depositing it on others. When a metal is severely strained, these films of eutectic will be also strained and in many places broken, thus allowing the actual crystals to come into contact with one another. The difference in the rate of etching of adjacent crystals and the phenomena of the electrolytic transfer, in an acid solution, of lead from one crystal to another in the same mass of metal, support the supposition that there is a difference of electric potential between the crystal faces which are brought into contact by severe strain. If it be assumed that a film of eutectic alloy when fluid, or even when in the pasty condition that precedes fusion, can act as an electrolyte, we may regard any two crystals thus in contact, with a film of eutectic interposed in places, as a very low resistance circuit, and the growth of the positive crystal at the expense of the negative would result. Moreover, such growth would be more rapid at higher temperatures, and its rate at a given temperature would vary in different specimens according to the nature and quantity of the impurities present. That an alloy can act as an electrolyte has not been established experimentally, but the assumption is supported by the close general analogy between alloys and salt solutions. This analogy extends to the very question of the growth of crystals, as Joly has shown that when crystals of a salt are immersed in their mother-liquor, growth of one at the expense of others will take place.

It should be added that solution of one crystal into the intervening film of eutectic, along with deposit on the neighbouring crystal from the eutectic, may occur as a consequence of differences of orientation, producing differences of "solution pressure" apart from actual electrolysis, but the fact that growth has not been observed to occur except in strained crystals favours the view that the action is electrolytic.

Some further results which have been deduced from the above hypothesis have been verified by experiment. It follows from the hypothesis that an inter-crystalline boundary containing no eutectic would be an impassible barrier to crystalline growth, but if the eutectic could in any way be supplied, growth across the boundary might take place. In an absolutely pure specimen of lead, there would be no eutectic at the inter-crystalline junctions, but as extremely minute traces of impurity would suffice to set up the action, it is almost hopeless to verify the hypothesis in this way. Some experiments on the cold welding of lead have, however, borne out these conclusions. Two clean, freshly-scraped lead surfaces will unite under great pressure in the cold state, and if a piece so welded be annealed, the crystalline growth due to the annealing, with very rare exceptions, never crosses the inter-crystalline boundary formed by the welding surface. To test whether the presence of some eutectic would allow growth to take place, small quantities of a more fusible metal were scattered over the freshly-scraped surfaces of lead before squeezing them together. Then, after a cold weld had been made by pressure, on annealing by exposure to 200° C. it was found that crystal growths frequently crossed the line of the weld, as the above theory led one to expect. This experiment has been repeated many times with the uniform result that whenever a small quantity of eutectic, or of an impurity capable of forming a eutectic with the lead, was scattered over the clean surfaces before welding, a distinct growth of crystals across the boundary took place as a result of annealing. On the other hand, a large number of welds were made without introducing any impurity, and with very rare exceptions they showed no growth across the boundary, even after the annealing process was continued for some weeks. In rare exceptions a minute amount of growth across the boundary was observed, but these may fairly be accounted for by the almost unavoidable presence of traces of impurity. The result as a whole goes far to confirm this solution theory of crystalline growth in annealing.

June 14.—"Static Diffusion of Gases and Liquids in Relation to the Assimilation of Carbon, and Translocation in Plants." By Horace T. Brown, F.R.S., LL.D., and F. Escombe, B.Sc., F.L.S.

This paper is intended to be the first of a series descriptive of the work carried out by the authors in the Jodrell laboratory on the fixation of carbon by green plants, and deals mainly with the purely physical processes by which atmospheric carbon dioxide gains access to the active centres of assimilation.

The new evidence which F. F. Blackman brought forward in 1895 in favour of the gaseous exchanges of leaves taking place exclusively through the stomatic openings, presents at first sight certain difficulties of a physical nature, which have led to an examination of the whole question of the free diffusion of carbon dioxide at very low tension, and under a set of conditions very different from those under which the previous determinations of the coefficient of diffusion of carbon dioxide and air have been made by Loschmidt and others, where the gases were initially of equal tension, and the ratios of mixture departed widely from those of ordinary atmospheric air. The inquiry has led to the discovery of some new facts connected with the static diffusion of gases and liquids, which are of considerable interest, not only from the physical point of view, but from the explanations they suggest of certain natural processes which are primarily dependent on diffusivity.

The method employed in the first instance for the determination of the diffusivity of atmospheric carbon dioxide was one of *static diffusion* down a column of air of a definite length towards an absorptive surface at the bottom of the column When a static condition has been established, there is a steady flux of the carbon dioxide down the air column which may be quantitatively investigated by the same simple mathematical treatment as the "flow" of heat in a bar when the permanent state has been reached, or the "flow" of electricity between any two regions of a conductor maintained at a constant difference of potential.

---

[1] It is proper to say that this hypothesis is due to Mr. Rosenhain.—J. A. E.

By a long series of experiments of this nature it was found that the diffusivity constant, $k$, for very dilute $CO_2$ does not materially depart from the value assigned to it by Loschmidt and others, when experimenting with much higher ratios of mixture, and that the difference is certainly not of sufficient magnitude to be taken into serious account in the study of the natural processes of gaseous exchange in the assimilating organs of plants.

In the static diffusion of a gas, vapour, or solute, as the case may be, the amount of substance diffusing in a given time, all other conditions being the same, is directly proportional to the sectional area of the column. It is found, however, that if the flow is partially obstructed by interposing at any point in the line of flow a thin septum pierced with a circular aperture, the rate of flow across unit area of the aperture is greater than it would be across an equal area of the unobstructed cross-section of the column at this point. If the margin around the aperture has a width of at least three or four times its diameter, the rate of flow is now found to be directly proportional to the *linear dimensions* of the aperture and not to its area, so that the velocity of flow through unit area varies inversely as the diameter.

A large number of experiments on the diffusion of carbon dioxide, water-vapour and sodium chloride in solution are given in support of this proposition. All these show that the rate of diffusion across such a septum, all other conditions being the same, is directly proportional to the diameter of the aperture, and not, as might have been expected, to its area.

Exactly the same result is obtained when small circular discs of an absorbent, such as a solution of caustic alkali, are surrounded by a wide rim and exposed to *perfectly still* air, the amount of carbon dioxide absorbed under these conditions being proportional to the *diameters* of the discs.

If, however, there are any sensible air currents the absorption becomes proportional to the areas.

These two sets of phenomena may be explained as follows:—

In the case of the absorbing disc in perfectly still air, the convergent streams of carbon dioxide creep through the air towards the absorbing disc, establishing a steady gradient af density, and this creep will be a flux perpendicular to the lines of equal density, which form curved surfaces or "shells" surrounding the disc and terminating in the rim. The state of things is exactly analogous to the electric field in the neighbourhood of a conductor of the same shape and dimensions as the absorbent disc.[1] In the case of the gas, the curves or "shells" of equal density are the analogues of the similarly curved surfaces of equipotential above the electrified disc, whilst the converging lines of creep or flux of the gas are the analogues of the lines or tubes of force which bend round into the disc as they approach it.

If we consider two such absorbent discs of different diameters, the curved surfaces in each system corresponding to a given density will be found at actual distances from the discs which are in the same proportion to each other as are the diameters of the discs. In other words, the gradient of density on which the rate of flow depends will be proportional to the diameters of the discs, which is exactly what is found experimentally.

This case of an absorbent disc is the exact converse of one which has been theoretically investigated by Stefan, viz. the conditions of evaporation of a liquid from a circular surface. He found that the lines of flux of the vapour proceeding from the surface of the liquid must be hyperbolas, whilst the curved surfaces of equal pressure of the vapour must form an orthogonal system of ellipsoids, having their foci, like the hyperbolas, in the bounding edges of the disc. This was a purely mathematical deduction which has never been verified experimentally, but it will be seen that the exactly converse phenomena of diffusion are in complete agreement with it.

In the other case of a diffusive flow through a circular aperture in a diaphragm, the lines of flow, which are *convergent* as they approach the aperture, bend round their foci situated in the edges of the disc and form a *divergent* system on the other side. If the chamber into which they pass is a perfectly absorbent one, and is sufficiently large, there will be formed on the inner side of the diaphragm a system of density shells similar to those outside, but with the gradient of density centrifugally instead of centripetally arranged. This system of shells is termed negative, and is as effective as the outer positive system in regulating the flow according to the "diameter law," so that this law will still hold good even if the outer air currents are sufficient to sweep away the external positive shells altogether.

All the known facts of diffusion through circular apertures in a diaphragm are in complete accord with the above explanation, which is fully elaborated in the original paper.

By diffusing colouring matter through apertures in a septum, under such conditions as to prevent convection currents, the "density shells" have been rendered visible, and it has been shown that their ellipsoidal form is exactly that which is demanded by the above hypothesis. Moreover, this method gives an experimental demonstration of the more rapid projection of the diffusing particles from the edges of the aperture than from a point nearer its centre, a fact completely in harmony with the deduction of Stefan regarding the evaporation of liquids under analogous conditions.

The various cases which present themselves in practice with regard to the rate of diffusion through single apertures in a diaphragm are then discussed from the above point of view, and simple formulæ for the determination of this rate for single and double systems of density shells are established: (1) for cases where the thickness of the diaphragm is negligible, and (2) for other cases where the apertures become more or less tubular. In a subsequent section of the paper it is shown how closely the observed facts conform to these deductions, and that in static diffusion through apertures in a septum we have a new and accurate method for the determination of the diffusivity constants of atmospheric $CO_2$, of the vapours of liquids, and of substances in a state of solution.

Since the velocity of the diffusive flow through unit area of an aperture in a diaphragm varies inversely with the diameter, it might reasonably be expected that a diaphragm could be so perforated with a series of very small holes arranged at suitable distances from each other, as to exercise little or no sensible obstruction when it was interposed in a line of diffusive flow, although the aggregate area of the small holes might represent only a small fraction of the total area of the septum. Multiperforate diaphragms of this kind were found to possess all the remarkable properties which had been anticipated.

The material used for the septa was very thin celluloid, which was perforated at regular intervals with holes of about 0·38 mm. in diameter. Details of a number of experiments with such diaphragms are given, in which it is shown that they may be so arranged as to produce but little obstructive influence on the diffusive flow of a gas when the total area of the apertures amounts only to about 10 per cent. of the area of the septum, and that nearly 40 per cent. of the full diffusive flow may be maintained when the number of the apertures is so far reduced as to represent an area of only 1·25 per cent. of the full area of the septum.

The explanation is to be found in the local intensification of the gradient of density in the immediate neighbourhood of the diaphragm, and which does not extend to the column away from the apertures. This disturbance of gradient is brought about by the rapid convergence of the lines of flux, and their divergence on the other side, with the consequent formation of a system of "density shells" over each aperture. A system of perforations of this kind may be compared with a system of conductors electrified to a common potential, the density of the diffusing substance above the apertures corresponding to electric potential, and the non-absorbing portions of the diaphragm to a surface formed by lines of electric force. Just as the electric capacity of a plate is not much reduced by cutting most of it away, so also is it possible to block out a large portion of the cross-section of the diffusing column without materially altering the general static conditions on which the flow depends.

The importance of these results in relation to diffusion through porous septa is next considered, diffusion through a thin porous septum being only an extreme case of free diffusion through a multiperforate diaphragm, whose apertures are so far reduced in size as to materially interfere with the mass movement of the diffusing substance.

A section of the paper is devoted to the application of these new observations to the processes of gaseous and liquid diffusion in living plants, and it is pointed out that the structure of a typical herbaceous leaf illustrates in a striking manner all the physical properties of a multiperforate septum. Regarded from this point of view it is shown that the stomatic openings and their adjuncts constitute even a more perfect piece of mechanism than is required for the supply of carbon dioxide for the physiological needs of the plant, and instead of expressing surprise at the comparatively large amount of the gas which an assimilating leaf can take in from the air, we must in future rather wonder that the intake is not greater than it actually is.

---

[1] The authors are indebted to Dr. Larmor for this suggestion of the electrostatic analogy.

From data afforded by actual measurements of the various parts of the stomatal apparatus of the sunflower it is shown that an extremely small difference of tension of the carbon dioxide within the leaf, as compared with that in the outer air, will produce a gradient sufficient to account for the observed intake during the most active assimilation.

It is also shown that the large amounts of water-vapour which pass out of the leaf by transpiration are well within the limits of diffusion, and that it is unnecessary to assume anything like mass movement in the outcoming vapour.

The translocation of solid material from cell to cell in the living plant is next considered, especially with reference to this transference being, at any rate in part, brought about by means of the minute openings in the cell-walls through which the connecting threads of protoplasm pass. Notwithstanding the very small relative sectional area of these perforations they probably exercise an important function in cell-to-cell diffusion, in virtue of their properties as multiperforate septa.

There are two appendices to the paper, one in which a full description is given of a series of experiments on the absorption of carbon dioxide by solutions of caustic alkali from air in movement; the second being devoted to a detailed description of the methods used for accurately determining the carbon dioxide absorbed.

**Physical Society**, June 22.—Mr. T. H. Blakesley, Vice-President, in the chair.—A paper, entitled "Notes on Gas Thermometry," by Dr. P. Chappuis, was read by Dr. Harker. The author having been led to recognise that hydrogen could not be used as a thermometric substance at high temperatures, on account of its action on the walls of the glass reservoirs, has had recourse to a constant volume nitrogen thermometer with an initial pressure slightly under 800 mm. The value of the coefficient of expansion of nitrogen at constant volume is variable, diminishing up to 80° C. and then increasing slightly. In fact, nitrogen at 100° C. behaves like hydrogen at the ordinary temperatures, its compressibility being less than that required by Boyle's law. A table of corrections was therefore prepared. The readings of the constant volume nitrogen thermometer are too low, but the corrections are small, amounting to about 0·04° C. at the temperature of boiling sulphur. The mean result of the author's experiments for the boiling point of sulphur is 445°·2 under a pressure of 760 mm. Callendar and Griffiths' results obtained with a constant pressure air thermometer is 444°·53. The difference is attributed to the joint action of several causes:—(1) The corrections for a constant pressure thermometer are about double those of a constant volume instrument. This correction applied to Callendar and Griffiths' result would raise it about 0·1°. (2) Callendar and Griffiths have used a value for the gas constant which is larger than that obtained by more recent experiments. Adopting the latter value, the boiling point would be raised to 445°. (3) The divergence may be due to the expansion of the reservoir. The most accurate way of determining this is by the interference method of Fizeau. This method is used with small pieces of the material, and the author has employed it to determine the coefficient of expansion between 0° and 100°. Extrapolation to 450° might cause errors The linear expansion has recently been determined by Bedford between 0° and 840° by a comparator method. The homogeneity of porcelain is doubtful, especially when glazed, and the great differences occurring between the expansions obtained from the above methods is attributed to the change in form of the tube in Bedford's experiments, brought about by unequal thickness and want of homogeneity and consequent unequal expansion. The author therefore adheres to his value of the boiling point obtained from the expansion by the Fizeau method, whilst recognising the uncertainty attaching to the application of the coefficient of expansion of the reservoir over an interval four times as great as that over which it was determined. —A paper on a comparison of impure platinum thermometers, by Mr. H. M. Tory, was read by Prof. Callendar. The object of this paper is to investigate the probable order of accuracy attainable in the determination of high temperatures by the use of ordinary commercial specimens of platinum wire. Five wires were compared, from 400° to 1000° C. The fundamental coefficients of the wires varied within 40 per cent. of the maximum value, but the temperatures observed by them when calculated on the platinum scale by means of the ordinary simple formula, did not differ by more than 9° at 1000° C. Each wire was directly compared with a pure standard wire, the two being wound side by side in the same tube. Curves have been drawn with the platinum temperatures of the standard wire as abscissæ, and the differences between the temperatures indicated by the two wires compared as ordinates. These curves are all straight lines, within the limits of observation, and hence the determination of two constants is sufficient to enable us to compare an impure platinum thermometer with the standard, and therefore with the scale of the gas thermometer. The two constants can at once be obtained from observations at the boiling point of sulphur and the freezing point of silver, and thus a practical thermometric scale can be established, which between 0° and 1000° never differs by more than two or three degrees from the gas scale.—Prof. Callendar said he was unable to agree with the correction to his observations suggested by M. P. Chappuis. He considered that the uncertainty in the coefficient of expansion of the gas was due to uncertain changes in the volume of the bulb, and to uncertainty in the coefficient of expansion of mercury. The fundamental coefficient of mercury was ·00018153 according to Regnault, ·00018216 according to the later reduction of Broch, and ·00018256 according to experiments by Chappuis with a hard glass bulb. It made a difference of no less than 4 per cent. in the fundamental coefficient of expansion of the glass, according as the original results of Regnault, or the value found by Chappuis, assuming the linear expansion of the glass, were adopted. The importance of the changes in the volume of the bulb had been fully pointed out, and a method of taking approximate account of these changes had been explained in the paper on the boiling point of sulphur in 1890. Unfortunately the glass employed was rather soft, and the changes of volume which occurred were too great to permit of the most accurate determination of the coefficient. The boiling point, when corrected for the smaller expansion of the bulb, came out lower than 444·53°. With regard to porcelain, Prof. Callendar did not consider it a good material, on account of the glaze. He did not think that the average coefficient of a tube or bulb over a large range of temperature could be inferred from a small and possibly asymmetric specimen. The results might be less inconsistent in the case of homogeneous and well-annealed metallic bulbs. The correction for the expansion of the bulb was, he believed, given by the expression $dt = (C + b\theta)t(t - 100)$. He did not agree with M. P. Chappuis that the correction was independent of $c$, although the value of $b$ was certainly most important at high temperatures. He also wished to take exception to the method adopted by Chappuis of calculating the correction of the nitrogen thermometer. According to Joule and Thomson, the correction should be greater; according to other authorities, it might be less. He hoped to discuss this in a further communication to the Society. Mr. Glazebrook said that, although he placed confidence in Chappuis' formula for a definite piece of porcelain between certain temperatures, he thought further and careful work was necessary before fixing on a formula for ordinary use. Prof. Carhart said he would like to see a comparison made between the results of experiments with gas thermometers and those with platinum and platinum-rhodium couples. Mr. Rose-Innes expressed his interest in the behaviour of nitrogen about 100° C., as mentioned in M. P. Chappuis' paper. Dr. Lehfeldt said the peculiarities of the nitrogen scale between 70° and 80° might be explained by the reversal of the properties of nitrogen between 0° and 100°.—A paper on the law of Cailletet and Mathias and the critical density was read by Prof. S. Young. The law of Cailletet and Mathias is very nearly, though in most cases not absolutely, true. It appears to be only strictly true when the ratio of the actual to the theoretical density at the critical point has the normal value 3·77. The curvature of the "diameter" is generally smaller the nearer this ratio approaches its normal value. The curvature is in nearly every case in opposite directions, according as this ratio is greater or less than 3·77. The curvature is generally so slight that the critical density may be calculated from the mean densities of liquid and saturated vapour at temperatures from about the boiling point to within a few degrees of the critical point with an error generally not exceeding 1 per cent. If, however, the critical density is calculated from the mean densities at low temperatures, the error may be considerable; in the case of normal decane it is between 5 and 6 per cent. The law does not, as a rule, hold good at all for substances the molecules of which differ in complexity in the gaseous and liquid states. Mr. Rose-Innes said that in his paper the author had used the generalisations of Van der Waals, although the author himself had shown that they were not strictly true. Prof. Young said that the generalisations held in some cases, although they did not in others. In all cases they were approximately true, and it was therefore advisable to use them, and study the results as far as possible.—The Society then adjourned until next October.

**Chemical Society**, June 7.—Prof. Thorpe, President, in the chair.—The following papers were read.—Condensation of ethyl acetylenedicarboxylate with bases and β-ketonic esters, by S. Ruhemann and H. E. Stapleton. Ethyl acetylenedicarboxylate reacts with benzamidine to form a substance of the probable constitution,

$$\begin{array}{l}\mathrm{CPh:N}\\ |\\ \mathrm{NH.CO}\end{array}\!>\mathrm{C:C}<\!\begin{array}{l}\mathrm{N:CPh}\\ \quad|\\ \mathrm{CO.NH}\end{array}$$

, which the authors term glyoxaline red.—Condensation of phenols with ethyl phenylpropiolate, by S. Ruhemann and F. Beddow. Sodium phenoxide reacts with ethyl phenylpropiolate, yielding a substance of the constitution $C_6H_5.C(OC_6H_5):CH.CO_2Et$; this ester is easily hydrolysed, and the acid readily loses carbon dioxide, giving phenoxystyrene, $CH_2:C(OC_6H_5).C_6H_5$.—The constitution of pilocarpine, by H. A. D. Jowett. Isopilocarpine yields on oxidation a lactonic acid of the constitution

$$\begin{array}{l}\mathrm{CH(CH_3)_2.CH.CH.CO_2H}\\ \qquad\qquad\quad|\quad\;\;|\\ \qquad\qquad\quad\mathrm{O{-}{-}CO}\end{array};$$

the alkaloid also contains the groups :NH and $:NCH_3$.—The nitrogen chlorides derivable from metachloroacetanilide and their transformations, by F. D. Chattaway, K. J. P. Orton and W. H. Hurtley.—The persulphuric acids, by T. M. Lowry and J. H. West. A quantitative study of the equilibrium established between sulphuric acid, hydrogen peroxide and "persulphuric acid" on mixing the former two substances, affords evidence indicating the existence of the acids $H_2O_2.4SO_3$ and $H_2O_2,2SO_3$ in a mixture of sulphuric acid and hydrogen peroxide.—On diphenyl- and dialphyl ethylenediamines, their nitro-derivates, nitrates and mercurichlorides, by W. S. Mills.—Derivatives of cyanocamphor and homocamphoric acid, by A. Lapworth. The halogen derivatives of cyanocamphor are reduced to cyanocamphor and homocamphoramic acid, $C_8H_{14}(CO_2H).CH_2.CONH_2$, by strong aqueous alkalis. α-Bromo-homocamphoric acid, $C_8H_{14}(CO_2H).CHBr.CO_2H$, made by heating homocamphoric dichloride with bromine, can be converted into homocamphoric acid,

$$\mathrm{C_8H_{14}}<\!\begin{array}{l}\text{——}\mathrm{CH.CO_2H}\\ \qquad\quad|\\ \mathrm{CO.O}\end{array}$$

.—The ultra-violet absorption spectra of some closed chain carbon compounds. II. Dimethylpyrazine, hexamethylene and tetrahydrobenzene, by W. N. Hartley and J. J. Dobbie.—A study of the absorption spectra of *o*-oxycarbanil and its alkyl derivatives in relation to tautomerism, by W. N. Hartley, J. J. Dobbie and P. G. Paliatseas.—Action of formaldehyde on amines of the naphthalene series (II.), by G. T. Morgan. The action of formaldehyde on ethyl-β-naphthylamine in cold acetic acid solution results in the formation of 2:2-diethyldiamino-1:1-dinaphthylmethane.—The bromination of benzeneazophenol (II.), by J. T. Hewitt and W. G. Aston.—Condensation of ethyl crotonate with ethyl oxalate, by A. Lapworth. Ethyl γ-oxalocrotonate, $CO_2Et.CO.CH_2.CH:CH.CO_2Et$, is formed by the action of sodium ethoxide on a mixture of ethyl crotonate and ethyl oxalate; it is converted into α-pyrone-α′-carboxylic acid,

$$\begin{array}{l}\mathrm{CH.CH:C.CO_2H}\\ \|\qquad\qquad\;|\\ \mathrm{CH.CO\,.\,O}\end{array}$$

, by hydrochloric acid.—Researches in silicon compounds. VI. On silicodiphenyldiimide and silicotriphenylguanidine, by J. E. Reynolds. On heating silicophenylamide, $Si(NHC_6H_5)_4$, the diimide, $Si(NC_6H_5)_2$, and silicotriphenylguanidine, $Si(NC_6H_5)(NHC_6H_5)_2$, are obtained.—Note on Bach's hydrogen tetroxide, by H. E. Armstrong.

**Linnean Society**, June 7.—Prof. Sydney H. Vines, F.R.S., President, in the chair.—Mr. R. Morton Middleton exhibited a letter, dated "London, 13 June 1788," in the handwriting of Sir J. E. Smith, addressed to Charles Louis L'Héritier, at Paris, in which he mentioned a visit to Oxford with Sir Joseph Banks and J. Dryander for the purpose of looking over the plants and drawings of Sibthorp, who was then lecturing there; and added some critical remarks on several species of *Sida* which L'Héritier had sent him for determination. Mr. Middleton also exhibited an engraved portrait of Sir J. E. Smith from the *Gentleman's Magazine*, 1828, which, with the letter, he presented to the Society.—Mr. F. Enock, with the aid of the lantern, exhibited several photomicrographs and photographs of living insects, and gave an illustrated account of the life-history and metamorphoses of a dragonfly (*Æschna cyanea*).—Mr. E. S. Goodrich read a paper, entitled "Notes on *Syllis vivipara*, Krohn." This worm, which he found in a tank at the Naples Laboratory, appeared to be identical with that described by Krohn in 1869 (*Arch. f. Naturg.* xxxv. p. 197), and in general form resembled Claparède's *Syllis Armandi* (probably *S. prolifera*, Krohn). The peculiar point of interest was its method of reproduction, the embryos growing within the body-cavity of the parent to an advanced stage (when they resemble the adult except in their smaller size and fewer segments), and escaping by the breaking off of the posterior portion of the parent's body.—Dr. Otto Stapf read a paper on the two Melastomaceous genera *Dicellandra*, Hook. f., and *Phaeoneuron*, Gilg. He showed that the differences between them are not in the heterandry and homœandry respectively, as was supposed, but in much more important characters which concern all those parts which affect the formation of the fruits and seeds. The diagnoses of the two genera must therefore be revised, with the result that *Phaeoneuron* and *Dicellandra* change their character as monotypic genera.—A paper was read by Miss A. L. Embleton giving a full account of the anatomy and histology of *Echiurus unicinctus*, received from Prof. K. Mitsukuri, of Tokyo.

### CAMBRIDGE.

**Philosophical Society**, May 7.—Prof. Clifford Allbutt, F.R.S., in the chair.—Exhibition of anomalous bones from predynastic Egyptian skeletons, by Prof. Macalister, F.R.S.—Ammocoetes a Cephalaspid, by Dr. Gaskell, F.R.S. The paper contained evidence that Ammocoetes was the living representative of the ancient Cephalaspids.—Note on some abnormalities of the limbs and tail of Dipnoan fishes, by H. H. Brindley. *Lepidosiren* and *Protopterus* sometimes exhibit partial bifidity of the limbs and tail. This condition of the limbs of *Protopterus* has received some speculative attention, and it has also been suggested that a branched limb of *Lepidosiren* might have a respiratory function. Boulenger and Howes have since shown that *Protopterus* may regenerate its limb in a branched condition, and sections of branched limbs of *Lepidosiren* show histological features clearly suggesting a reproduced condition. Budgett and Kerr have noticed a considerable tendency to injury and reproduction of limbs and tail in both these fishes—and there can be no doubt that the reproduction is often bifid. A parallel is therefore afforded with the bifidity sometimes seen in lizards' tails, which in all cases examined are reproduced structures. In some of the latter there is evidence that the extra tail is a new growth arising from an injured place, and in others that the new growth is bifid from its commencement. In the cases of *Lepidosiren* examined the latter condition alone seems to hold.—On the standardisation of anti-venomous serum, by W. Myers. It was shown that Calmette's method was based on views which were no longer tenable; and, further, that a special mixture of snake venoms is required. A more accurate measure of the antitoxin was to test its neutralising power, using ten times the minimal lethal dose of unheated Cobra poison, and mice of 15 grams weight as test animals. With this method it was possible to estimate the serum to within 15 per cent.

**Royal Meteorological Society**, June 20.—Dr. C. Theodore Williams, President, in the chair.—Mr. W. Marriott read a paper on rainfall in the west and east of England in relation to altitude above sea-level. This was a discussion of the mean monthly and annual rainfall for the ten years 1881-90 at 309 stations which the author had grouped according to the altitude of the stations above sea-level. The western stations were considered to be those which drained to the west, and the eastern stations those which drained to the east of the country. The diagrams exhibited showed that there is a general increase in the annual amount of rain as the altitude increases, and that the rainfall is considerably greater in the west than in the east. The monthly diagrams brought out prominently some interesting features, among which were (1) that the monthly rainfall in the west is subject to a much greater range than in the east; (2) that in the west the maximum at all altitudes occurs in November, but in the east it is generally in October; (3) that in the west the spring months, April, May and June, are very dry; and (4) that both in the west and east there is a very great increase in the rainfall from June to July.—A paper by Mr. J. Baxendell was also read, giving a description of a new self-recording rain-gauge designed by Mr. F. L. Halliwell, of the Fernley Observatory, Southport. This rain-gauge, which the author believes approaches very closely to an ideal standard, has also the merit of being constructed at a moderate price.

### PARIS.

**Academy of Sciences**, June 18.—M. Maurice Lévy in the chair.—On the monument erected to Lavoisier, by M. Berthelot. The monument is now finished, and will be unveiled on July 27. —The problem of the cooling of the earth's crust treated from Fourier's point of view, but by a much simpler method of integration, by M. J. Boussinesq.—Actinometric observations during the eclipse of May 28, by M. J. Violle. A diagram of the results obtained is given which closely approximates to the theoretical curve, the divergence being mainly due to the lag of the instrument, but also apparently in part owing to an absorption of heat by the solar atmosphere. The minimum ratio deducted from the observations was 0·12, distinctly less than the ratio of the radiant surfaces, 0·14. Two sets of observations were carried out, one on the Pic du Midi, at a height of 2860 metres, and the other from a balloon, at a height of about 10,000 metres.—On the formation of nitric acid in the combustion of hydrogen, by M. Berthelot. Hydrogen was burnt from a jet in oxygen containing varying amounts of nitrogen, and also in the calorimetric bomb at pressures of from one to twenty atmospheres, and the amounts of nitric acid formed determined. The proportion of nitric acid formed was greatest in the bomb, and increased with the initial pressure of the gases.—The combustible gases of the atmosphere: the air of towns, by M. Armand Gautier. Air is drawn, after careful purification from dust, moisture and carbon dioxide, over red-hot copper oxide, and the amounts of water and carbonic acid determined. The mean results for twenty-two days was 1·96 mgr of hydrogen and 6·8 mgr. of carbon per 100 litres of air; but these quantities become 3·96 mgr. and 12·45 mgr. respectively when a correction is applied for the incomplete combustion effected by the particular length of copper oxide used.—The last eclipse of the sun and the zodiacal light, by M. Perrotin.—The occultation of Saturn by the moon of June 13 last, by M. Perrotin.—On the formation of beds of stipite, brown coal and lignite, by M. Grand'Eury. In the formation of brown coals marsh plants were the chief factor, trees only occurring rarely.—M. Dwelshauvers-Dery was elected a Correspondent for the Section of Mechanics, and M. D. P. Œhlert a Correspondent for the Section of Mineralogy.—Observations of the total eclipse of the sun of May 28 last, made at Argamasilla, in Spain, by M. H. Deslandres. The work undertaken included the measurement of the velocity of rotation of the corona, and the examination of its ultra-violet spectrum; the study of the ultra-violet spectrum of the reversing layer; the calorific spectrum and the direct photography of the corona.—The partial eclipse of the sun of May 28, at the Observatory of Toulouse, by MM. Montingerand, Rossard and Besson. The results obtained were confined to direct observation of contacts, measurement of the common chord, photographic observations and the knowledge of meteorological phenomena. —The total eclipse of May 28 studied at Elche, by M. J. C. Sola. Photographs of the spectra of the chromosphere and corona were taken.—Observations of the shadow fringes made during the total eclipse of the sun of May 28, by M. Moye.—On the uniform integrals of the problem of *n* bodies, by M. Paul Painlevé.—On the general theory of rectilinear congruences, by M. A. Demoulin.—On the expansion of fused silica, by M. H. Le Chatelier. The mean coefficient of expansion of fused silica for a temperature range of 0° to 1000° is 0·000,0007, the smallest coefficient known for any common substance.—Action of oxidising agents upon alkaline iodides, by M. E. Péchard. A study of the interaction of alkaline iodides with potassium permanganate, sodium periodate, potassium manganate, ozone and hydrogen peroxide.—Study of the viscosity of sulphur at temperatures above the temperature of maximum viscosity, by M. C. Malus.—On the selenides of iron, by M. Fonzes-Diacon. Several selenides of iron can be prepared of the composition indicated by the formulæ $FeSe_2$, $Fe_2Se_3$, $Fe_3Se_4$, $Fe_7Se_8$, and FeSe. They are attacked by hydrochloric acid with difficulty, $FeSe_2$ being unaffected by this reagent.—The true atomic weight of boron, by M. G. Hinrichs. From two analyses of boron carbide made by M. H. Gautier, the author concludes that the true atomic weight of boron is exactly 11.—Action of sulphur dioxide and hydrogen sulphide upon pyridine, by M. G. André. Sulphur dioxide gives a crystalline compound with pyridine, $C_5H_5N.SO_2$, and the action of suphuretted hydrogen upon this gives pyridine trithionate and tetrathionate. —On the αβ-dimethylglutolactonic acids, by M. E. E. Blaise.—On the reserve carbohydrates in the seed of *Trifolium repens*, by M. H. Hérissey. A mannogalactane was isolated from the seeds of *Trifolium repens*, resembling in its properties the carbohydrates obtained from lucerne and fenugreek.—Presence of iodine in the blood, by MM. E. Gley and P. Bourcet. Iodine was found to be present in the blood of dogs in amounts varying from ·013 mgr. to ·06 mgr. per litre of blood. The iodine is in the liquid portion of the blood existing combined with proteid matter, analogous to the iodine in the thyroid gland.—Reality of urinary toxicity and of autointoxication, by M. A. Charrin.—On the anticoagulating power of serum in the pathological state, by MM. Ch. Achard and A. Clerc. Human blood serum, when present in sufficient quantity, prevents the coagulation of milk by rennet, the quantity of rennet solution required to produce coagulation measuring the activity of the serum. The anticoagulating power of the serum is unaffected by many diseases, but in others, such as pneumonia, septicemia with acute nephritis, uterine cancer, and advanced tuberculosis, this power is reduced to one-half or even less.

### CAPE TOWN.

**South African Philosophical Society**, May 2.—L. Péringuey, President, in the chair.—Mr. Sclater exhibited a portion of a bone found at a considerable depth below the surface in Grave Street, and presented to the Museum by Col. Feilden. The bone was obviously the upper portion of the radius and ulna of a large ungulate animal; it appeared to be too large for an ox, and Mr. Sclater suggested that it might perhaps be that of a hippopotamus.—The Rev. Dr. F. C. Kolbe read his paper, entitled "Ultimate analysis of our concept of matter." The lecturer first briefly stated the four prevailing views on the subject—the mechanical, the dynamic, the vortical, and the scholastic or Aristotelian. The first two theories being for various reasons rejected, the lecturer stated that the purpose of this paper was to reconcile the third and fourth.

## PROTOPLASM.

*Allgemeine Biologie.* By Prof. Dr. Max Kassowitz. Vols. i. and ii., Pp. xv + 411, and x + 391. (Vienna: Moritz Perles, 1899).

A BAD hypothesis is better than none at all, is a saying of which many have taken advantage; but able minds have agreed with the substance of the remark, and few can dissent from it in connection with that everlasting puzzle—Protoplasm. It is in vain to inveigh against the uselessness of speculations as to the structure or constitution, nature—what you will—regarding the physical basis of life, or regarding attempts to picture, however roughly, the movements, rearrangements and evolutions in that veritable witches' dance, the quadrilles of the molecules in which life consists. The inquiring mind is so constituted that it cannot resist the temptation to fashion some rough hypothesis as a tool wherewith to make one more attempt to pick the lock which hides the secret, and the criticism of the serious as to the futility of his efforts is no more powerful than the epigram of the debater to prevent him returning to the ruins of previous speculations, with renewed efforts to rebuild his frail image of something approaching, as nearly as may be, the inconceivably complex, and exposing it once more to the blows of the critic.

To those who are hopeless, let the more hopeful point out the difference in our present ideas of the nature of protoplasm from those of twenty years ago, and say whether no advances have been made.

In this extraordinarily well-written work, it is satisfactory to see that the word Biology is used in the sense of "the science of life," and not in the restricted and often unintelligible way so common in Continental works. Still more satisfactory is it to find here a carefully thought out plan of re-examination of the fundamental phenomena of life, and of "the physical basis of life," on which is erected a hypothesis with bold outlines and stately proportions, yet carefully and minutely fitted details, in conformity with the rapidly advancing knowledge of the last two decades.

The subject of "Allgemeine Biologie," as treated by the Viennese professor, resolves itself under the following headings:—

I. "Aufbau und Zerfall des Protoplasmas," forming the theme of the first volume, which is further subdivided into: (1) "Das Problem des Lebens und die Versuche zur Lösung desselben"; (2) "Aufbau des Protoplasmas"; and (3) "Zerfall des Protoplasmas."

II. The second volume is entitled "Vererbung und Entwicklung."

The third and fourth volumes are not yet to hand, but we are informed that they will deal with "Stoff- und Kraftwechsel der Thiere" and with "Nerven und Seele" respectively. That they will be eagerly looked for by all who have read the two at present under review is a safe prophecy.

Kassowitz takes his stand on the conviction—the reasons for which are given at great length in the first half of the first volume—that previous hypotheses as to the nature of protoplasm, based on assumptions that any structure visible after treatment can be translated in terms of its structure during life, break down on examination equally with those which would regard protoplasm as a mere emulsion; and that all attempts to explain what is going on in living protoplasm, which have for their basis the assumption that oxidations, reductions, and metabolic changes generally are carried out in the fluids bathing any such machinery of the protoplasm also fail to withstand criticism. The thermodynamic theory of life fails because the engine itself burns, and the value of a substance as food has no relation to its combustible value. It might have been added that Pfeffer had already shown this in his treatise "Zur Energetik der Pflanze." The osmotic theory of the botanists breaks down, because it attributes to the cell-sap an importance which a mere solution under such conditions does not possess; the fermentation theory fails to explain more than a few bye-phenomena of life, and has no help for us in questions concerning synthesis; the electro-dynamic theory breaks down because electric phenomena are least obvious just where we should most expect them. The molecular-physical theory assumes vibrations and the shaking asunder of molecules which are so stable that it is impossible to believe that they could be shattered and others escape under the conditions imposed; while the vitalistic theory is a mere confession that what is to be explained needs explanation.

Underneath or behind all the assumptions of micellæ, gemmules, biophores, determinants or other formed structural units, as well as all material networks, rods, spherules, fibrils, pellicles and foams, Kassowitz detects the question—Of what are these physiological units and structures composed? And he regards the fundamental fallacies underlying all previous hypotheses regarding the constitution and working of living protoplasm as chiefly two:—viz. the assumption that protoplasm is composed of proteids built up into some sort of more or less stable machinery, and that the chemical and other changes usually comprised in the term metabolism are carried on outside or merely in contact with this machinery—*e.g.* in a meshwork, or on the surface of the physiological units.

He therefore proposes to examine in detail, and step by step, what comes of deductions made from the hypothesis that protoplasm consists of molecules, in the chemical sense, but of extreme complexity, large volume, and very labile, linked one to another in series, and each requiring for its construction, not only proteids, but also fats, carbohydrates and the mineral salts known to be indispensable for life. And that every vital act consists in destructions and reconstructions of these molecules.

To obtain a coarse picture of this invisible structure we may suppose extremely tenuous fibrils of india-rubber joined up into a complex network and bathed in a fluid which contains the necessary ingredients for putting in new pieces wherever, by stretching the net too far, we break the elastic strands; such breakages will occur especially between the nodes, and immediately the gaps are bridged over again by new fibrils, or networks of such, further extension, breakage and restitution are possible.

The linked up chains and networks of protoplasm-molecules—which do not correspond to the networks of coagula of other hypotheses—are termed *stereoplasm*, the bath of liquid containing proteids, carbohydrates, fats, minerals, molecular oxygen, etc.—*i.e.* in which are dissolved all the food-materials as well as all the products of shattered molecules—is termed *hygroplasm*. The osmotic attraction for water of the newly formed molecules (imbibition) would set up pressures resulting in such ruptures of the linked up series.

Kassowitz supposes that every molecule of the *stereoplasm* is liable to disruption when stimulated by any mechanical shock, chemical reaction, thermal or electrical radiation, &c., and that the immediate results of the shattering of a given molecule are somewhat as follows. The products of disruption are partly atom-groups which at the moment of disruption display unsaturated affinities of so energetic a character that they split the molecules of atmospheric oxygen brought into the hygroplasm and combine to form saturated compounds such as $CO_2$ and $OH_2$; partly atom-groups containing nitrogen, which rearrange themselves into bodies such as proteids, and can be utilised again in building up new protoplasm-molecules, or temporarily stored, or excreted bodies of various kinds.

The combustions involved in the formation of $CO_2$ and $OH_2$, and constituting respiration, of course result in the evolution of heat: they are, in fact, explosions, and each such explosion acts as a new stimulus and shatters more protoplasm-molecules, with results and consequences as before, and it is this repeated play which constitutes the propagation of a stimulus—either irregularly in all directions or, if the stereoplasm is linked up more especially along certain tracts (nerves), in definite directions. The accumulation of metabolic products may result in blocking the meshworks, and so impeding the access of oxygen, and the activities slow down accordingly. In the pauses of rest between such destruction changes, the building up of new protoplasm-molecules is accomplished, and this act of restitutive construction is *assimilation*, while the interposition of the new molecules between those already in existence is *growth*.

In illustration of the kind of forces at work in the construction of a new protoplasm-molecule by assimilation, Kassowitz points to such phenomena as selective crystallisation, whereby a minute crystal of Glauber's salt, for instance, in a mixture of the same substance and saltpetre induces the crystallisation of the former only; and to such cases as mixtures of two optically active salts in which the crystallisation of one only is determined by introducing a minute crystal of like optical activity, and to other cases where substitutions of one atomic group by another can be brought about. These illustrations are not intended to serve as examples of what happens, but to show that the forces concerned in chemical attractions may well be those at the bottom of the phenomena of assimilation of like to like in the stereoplasm, or of the building up into the complex molecule of protoplasm of atom-groupings of similar or not very dissimilar nature; and although we have no hope of following the various stages in detail, it is argued that stereochemistry has at least taught that forms and configurations may result from such molecular phenomena as those indicated.

The arguments to show that the unstable protoplasm-molecule, the lability of which is increased by radiant energy absorbed from without, is itself devoid of oxygen, is capable of reducing highly oxidised food-substances, of absorbing water and setting up osmotic phenomena, of giving rise to metabolites of various kinds, &c., &c., are too long to reproduce here, and I must content myself with one illustration only, of the many given in the remainder of the first volume, to show the application of the hypothesis to special cases.

When the pseudopodium of an *Amoeba* has reached a certain development it suddenly retracts, or rather collapses, for Kassowitz regards the phenomenon as a rapid tumbling to pieces of the molecular structure, owing to stimulation: certain protoplasm-molecules are shattered, atom-groupings of carbon and hydrogen split the molecular oxygen and are at once burnt to $CO_2$ and $OH_2$, the heat-vibrations evolved during the combustion shattering more molecules, and so on, throughout that part of the mass. This process exhausted, a period of restitution sets in, and new molecules are built up from the fragments of proteids, carbohydrates, fats and mineral substances at disposal, and become interpolated between those which had escaped destruction, and a new pseudopodium is put out by assimilative growth. Among other arguments for the view that this is really a process of growth, Kassowitz points out that the rate of protrusion of such a pseudopodium, rapid as it appears under a high power, is really not much more rapid than the growth of a stem of asparagus, a mushroom or a bamboo.

The most interesting part of the second volume will, for most readers, be those dealing with the questions of variation and evolution.

Having elaborated his theory of the essential structure and mode of working of protoplasm, Kassowitz proceeds to consider the complexities which arise, first, on the differentiation of the nucleus and "germ-plasm," and then on the further divisions of labour involved in multicellular organisation. In these cases the nucleus, internal cells, &c., obtain for their immediate environment, not the outer world, but protoplasm exposed to the action of the latter and modified by it. Whereas undifferentiated protoplasm obtains its supplies of food and energy direct from the environment, the nucleoplasm can never do this, as it never comes in contact with it. Its protoplasm-molecules must select their assimilable materials from the fragments of shattered cytoplasm molecules, and *if any modifications in the modes of disruption and reconstruction of the molecules of the stereoplasm—i.e.* in the "somatoplasm" of authors—*have been brought about by the action of the environment*, the slightly altered atomic groupings and modes of disruption thus put at the disposal of the nucleoplasm—*i.e.* the "germ-plasm" of authors—will affect the building up and modes of disruption of the new molecules of this, and these in their turn react again, and so on.

This short summary of a long argument must serve to indicate the nature of the author's grounds for concluding that Weissmann's contention against the transmission of acquired characters cannot be upheld. It is also the basis on which Kassowitz founds his theory of variation, which latter he regards as always due to the action of the environment, translated in slight differences in the mode of breaking down and reconstruction of protoplasm.

It is impossible to summarise vol. ii. in a review with any hope of doing justice to the criticisms—some of them undoubtedly clever—of contemporary writers on evolution, Weissmann especially coming in for lengthy and severe treatment, particularly with regard to the theory of determinants, and his peculiar views on the meaning of amphimixis, natural selection, and acquired characters. It must suffice to say that Kassowitz offers—assuming the validity of his fundamental hypothesis—what he regards as convincing arguments to prove the essential truth of Darwin's conclusions as to the inheritance of adaptations, of the effects of use and disuse—in short, of the gradually accumulated effects of the environment on the somatoplasm, until the latter is so altered as to affect the germ-plasm, and so fix and hand on the changes.

The author regards the theories of pangenesis and their like, equally with such as Haeckel's suggestions as to transmissions of modes of vibrations, as far too complex: his chief objections are that it is to him inconceivable how every structural part could be represented by a physical unit or by a mode of motion transferred to the germ-plasm, and that he cannot see how those who conceive this can get over the difficulty that such vibrations would annul each other as their paths cross, or that the pangenes, biophores, determinants, &c., would get lost on the road. Further, these latter units are, by hypothesis, themselves living, and hence the real difficulty is only shelved.

Kassowitz, however, only demands of his germ-plasm that it be made up of a certain, and probably not a very large number of similarly built and very complex, but not infinitely complex, molecules. He does not suppose that every form-unit of the future organism is represented, but that certain characteristic atom-groupings out of the chemical units of the somatoplasm are utilised in the architecture of the molecule of the germ-plasm, and that in ontogeny these atom-groupings make their effect felt, either directly or indirectly, by the way of correlations of various kinds.

This is true epigenesis. In the developing organism every part is formed anew, from a substance in which none is especially represented. The forms and arrangements which ensue are simply the results of the activities of the atom-groupings already there, working on the materials supplied. When these latter have been assimilated—*i.e.* built up into protoplasm molecules—they exert their cumulative effects on more substance, and also *modify those already present by serving as new environment*—and so the process of evolution proceeds. Every now and again a slight variant gets its play, and the results may be far-reaching; but, on the whole, the dominant play of the constellations of molecules at work leads to what we term uniformity—a relative term.

While fully appreciating and endorsing Darwin's conclusions as to the importance of artificial selection, Kassowitz appears to undervalue the power of natural selection, curiously enough, because he, like so many others, cannot imagine it to be effective in the early stages of adaptive changes. He thinks acquired characters must have reached a certain stage of perfection before natural selection can come into play, and argues that when such a stage is reached selection is unnecessary, because so many individuals have already got the adaptation. Kassowitz appears to me to here betray the position of a laboratory philosopher as opposed to a field-naturalist. His own hypothesis points to the laborious accumulation of the effects of repeated stimuli and repeated readjustments: some have survived, others and far more have perished—is this not natural selection? There seems to be some confusion of thought expressed in implications that natural selection is incompetent to explain the *origin* of variations, which primarily it was never intended to do.

In one or two cases, indeed, the Viennese professor appears to me to have completely misunderstood the position—to an extent so remarkable that the question obtrudes itself, whether the whole argument must not be vitiated into which such misapprehension has crept. To quote one instance only. He admits that the struggle for existence between closely allied varieties, races, or species has resulted in the death of some races, &c., but objects that many plants and animals in the past

> "nicht auf diesem Wege ihren Untergang gefunden haben, sondern durch ungünstige äussere Bedingungen und feindliche Einwirkungen, also durch Trockenheit, Ueberschwemmung, Kälte, Nahrungsmangel oder überlegene Feinde vernichtet wurden, dass sie also nicht im Concurrenzkampfe, sondern in einem mit ungenügenden Mitteln geführten Abwehrkampfe unterlegen sind" (vol. ii. p. 131).

But what does all this imply if not selection due to the environment, and the struggle for existence?

To find a paragraph like this followed by the question—Is it conceivable that such struggle for existence can have led to any adaptive arrangement whatever? almost takes away one's breath, because it is so totally beside the issues raised by Darwin. The only explanation appears to be that Kassowitz must be combating some foreign misinterpretation of the views of the great master. In spite of these and other faults—I take it, no botanist will accept the explanation of geotropism (vol. i. p. 280)—this remarkable book appears to me to be a valuable contribution to the literature of evolution, well worth reading if only for the numerous criticisms and suggestions scattered throughout its fascinating pages. These, by the bye, are not few—there are nearly 750 pp. of text, and more than that number of notes. It may be that the glamour of the style and the beauty of the theme have led me to pass too lightly over the failings, and to over-estimate the good; but the good is there.

We have heard much of late about useful knowledge. From the point of view of those who regard all knowledge as "useless" which cannot be directly applied to the material improvement of man, the books before me are indeed of little worth; but to those who draw distinct lines between knowledge and learning—information and education—no apology will be needed for the conviction that a treatise of this kind is especially welcome at the present time. It is not only instructive, but stimulating to a degree, and of the highest educational value to the biologist of to-day.

H. Marshall Ward.

## PITMANESE PHONETICS.

*Introduction to English, French, and German Phonetics, with Reading Lessons and Exercises.* By Laura Soames. New Edition revised and edited by Wilhelm Vietor, Ph.D., M.A. Pp. xxvii + 178 + 89. (London: Swan Sonnenschein and Co., Ltd., 1899.)

THIS new edition of Miss Soames's work, which was designed by the authoress to provide a convenient method of teaching the pronunciation of the English, French and German languages, will no doubt prove useful to those teachers who believe in the advisability of teaching pronunciation by means of Pitmanese. The book is in no sense a scientific treatise on phonetics; the portion which deals with the production of the sounds of the the three languages treated of is simply a very good and useful exposition of the obvious: the main point of the book is the elaboration for teaching purposes of a phonetic alphabet which in many respects falls far short of our ideal of what a phonetic alphabet should be, if such a thing need be constructed for teaching or any other purpose at all, except for the use of scientific students of linguistic phenomena. *E.g.* the authoress uses "*a*" to express the indeterminate vowel-sound: now nobody ever pronounced *the* as "dha"; when it is not fully pronounced "dhî," it is pronounced as a German would pronounce "dhö": to write it "dha" is most misleading. Also, the final *-er* in English absolutely = the German ö; *crozier* is pronounced "krōzyö," though Miss Soames would tell us to pronounce it "krōzhar." She writes *gardener* as "gâdnar": now if we pronounce a true *r* in *gardener* at all, it is most certainly in the first syllable (where it is usually sounded as a faint guttural, a sort of feeble *ayin*), and *not* at the end of the word: *gârdnö* or *gâ'dnö*. Generally speaking, Miss Soames connives at the tendency of modern English to weaken the *r*, and represents it as being far weaker than it really is: in the same way the tendency to lose the distinction between *witch* and *which* is in no way combated by Miss Soames. She spells, most inconsistently, "when," "which," instead of "hwen," "hwich" (hwič), the proper phonetic spelling. Again, to teach a child to pronounce *Sassenach* as "Sas*i*næ*k*" (Pt. i. p. 109), and *Lochinvar* as "Lo*k*invar" (Pt. ii. p. 64), is an extremely slipshod proceeding, if it be not a mere solecism on the part of the authoress.

In the German phonetic spelling one or two weak points may also be pointed out. The expression of hard *ch* by *x* is a mistake: this appears to give the ordinary symbol for *ks* in the Latin alphabet a value which it does not possess: every learner cannot be expected to know that the Greek Χ (Russian х), which does possess the value of hard *ch*, has been transported into Miss Soames's phonetic alphabet to express this value. It would have been better to have used the small Greek type and have written *Nacht* "Naχt," not "Naxt." We do not like the adoption of ç to represent final *-g* after front vowels and consonants, as in *Sieg*, *Berg*, &c., either; a wrong primary impression is again given, and the fact is lost sight of that it is an *h*-sound, not a *k*-sound, which is in question. Why not use the symbol well-known in the transliteration of Egyptian and Assyrian, ḫ, for this sound, keeping χ for hard *ch* and final *-g* in *Tag*, &c.? *Sieg* would then be phonetically written "Zîḫ." Miss Soames also made ç stand for the *ch*-sound in *manches*; this is incorrect, *ch* here = "hy" ("mânhyez"), a sound quite distinct from the final -ḫ of *Sieg*.

The authoress appended a list of "Loan words used in English," a large portion of which is made up of words and phrases which are not loan words at all; *e.g. ancien régime* (!), *abattoir* (!!), and *Aphrodite* (!!!). On the other hand, such words as *abatis*, *accolade*, *aegis*, or *aiguillette* (which is presumably what the authoress means by "aiguille"), *are* loan words. In this list some mistakes of pronunciation occur, *e.g. a fortiori* should be pronounced on Miss Soames's system "ey fôrtiô'rai," not "fôshiô'rai," a vulgarism which no person with the slightest intelligent knowledge of Latin would ever think of using; *anacoluthon* should be pronounced "ænako'lû'tho'n, sounding the *o*, not "ænako'lyû'than"; *Canaan* "Kanâ'an," not "Keynan"; *Koran* "Karân," not "Kôrân"; and *sheikh* "shêç" (German "Scheech"), not "shîk," which is a terrible mispronunciation. On p. 104, *Eisteddfod*d is given a superfluous final *d*; and on p. 99, the misprint *Bacch*as is noticeable.

On the whole, while this work may be regarded as generally useful for the purpose for which it is intended, it is unluckily marred by a tendency to perpetuate many incorrect and vulgar pronunciations, and even by several mistakes, some of them merely slipshod, others due to ignorance, which the reviser ought to have corrected.

---

## OUR BOOK SHELF.

*Psychologie der Naturvölker.* By Dr. J. Schultze. Pp. xii + 392. (Leipzig: Veit and Co., 1900.)

IN this study of primitive culture, Dr. Schultze passes under review, from the standpoint of the psychologist, the material which is the common heritage of the anthropologists of to-day. Spite of the suspicions aroused by a sub-title of nineteen words, Dr. Schultze's volume is an unpretentious bit of work by a competent writer, whom no phantasy of construction or love of paradox has led astray from the patient use of authorities and the exercise of a sober judgment. Dr. Schultze's first essays in his subject were printed some thirty years ago. The present contribution is self-contained, though for its author it is but a part of a larger whole, preluded by physiological psychology and a treatise on the psychical life of plant and brute, and to be followed by a study of childhood. It is naturally evolutionist in conception, although the descriptive continuity which the author maintains is accompanied by the refusal to allow that the derivation of apperceptive consciousness from associational, which in the interests of a unitary view of nature he might desiderate, has been adequately made out. A feature of the book is the use made of English authorities. Not only Spencer and Tylor, but McLennan and Lubbock supply the writer with important doctrines, *e.g.* in his account of the evolution of marriage. Mr. Sutherland's "Origin and Growth of the Moral Instinct" is recognised as having anticipated Dr. Schultze in much which he would have been glad to have said, but, far from being dismissed with a *pereat*, is summarised in an appendix. It is on fetichism and animism that Dr. Schultze is most at home. Not that there is not much else of interest on the alleged superiority of vision among savages, on the concreteness of their philology, on the relation of rhythm to melody, on the difference of the sexes in regard to the sense of smell, on the evolution of the sense for landscape, and the like. But to the topics of his earliest studies he returns as to a first love. On the soul-theories of savages and the corresponding eschatology he writes convincingly. The plurality of souls in pulse and blood and breath and shadow, the gradual elimination of some of these and the syncretism of the rest, the place of the dream image in the evolution of the cult of *manes* and in the selection of totems, the literal and unsymbolic character of the latter, the order in which the heavenly bodies enter into primitive worship—these are the points on which Dr. Schultze compresses year-long work into moments of insight and selective description. Believing, as he does, that Germany has a colonial future in direct contact with primitive stocks, Dr. Schultze offers his essay to the understanding of the savage as a help forward to the achievement of the educational mission of his country. A pious gift. H. W. B.

*The Study of Bird-Life.* By W. P. Pycraft. Pp. 240. Illustrated. (London: George Newnes, Ltd. 1900.)

THIS little volume belongs to "The Library of Useful Stories," now in course of issue by the publishers; and although it must have been difficult to compress a general review of the leading facts of bird-life into such a small compass, the author may be congratulated on the success of his attempt. As Mr. Pycraft is a morphologist rather than a systematist, it would naturally be expected that he would incline rather to the morphological and phylogenetic aspects of his subject, and this we find to be the case. We have, for example, an excellent chapter on the morphology of the bird's wing, while two others treat of avian pedigree, and a third is devoted to the distribution of birds in space and time. Perhaps the most specially interesting chapter in the volume is the one dealing with the flightless birds and their fate, since this is a subject on which the author is peculiarly qualified to speak with authority.

Although, of necessity, written from a purely popular standpoint, the volume contains many passages which are well worth the attention of the scientific ornithologist. If there be a fault, it is the introduction of irrelevant matter, the place of which might have been better occupied by details pertaining to the subject in hand. And if a second edition be called for, the author will perhaps be inclined to modify the statement in the tenth chapter, that "the kind of rock" in which bird-remains are found is sufficient to give a notion "of the bird-life of that particular period of the earth's history." R. L.

*An Introduction to the Differential and Integral Calculus and Differential Equations.* By F. G. Taylor, M.A., B.Sc. Pp. xxiv + 568. (London: Longmans, Green and Co., 1899.)

THE appearance of still another treatise of this kind shows how earnest and how prevalent is the desire to introduce students of physics to a knowledge of the calculus at as early a stage in their career as possible.

The author has studied simplicity of treatment, but has evidently striven to secure accuracy as well as clearness and distinctness in his exposition of the principles of the subject. A special feature, which will be of great advantage to the ordinary student, is the detailed discussion of numerous examples.

Interspersed throughout the several chapters the student will also find an abundance of not too-difficult exercises carefully graduated and with answers appended.

A fair and not excessive amount of space is devoted to the subject of curves, and the illustrative diagrams are distinctly drawn.

The section on the integral calculus concludes with applications to volumes and surfaces of revolution, centroids, and moments of inertia.

The last section of the book forms a good introduction to the methods of dealing with ordinary differential equations of the first and second orders.

## *ENGLAND'S NEGLECT OF SCIENCE.*

JUST before the first movement organised by Lord Roberts there was probably not one thinking person in England who was not ready to vote for an immediate change in all sorts of English methods of doing things. Consequently everybody was willing to listen to the advice of men who had for years been crying in the wilderness and prophesying disaster. Now, however, that we have worried through our military trouble, we shall probably feel so much ashamed of our intense fright as to put aside most of our desire for reform, and even to have less thought of it than before the war began. It is, therefore, the duty of those who have earned the right to a hearing to prevent the nation from sinking down into its sleepy acquiescence with old methods of working; and I am glad to see that Sir Norman Lockyer, in his speech at the Royal Academy dinner, referred to scientific education as a great, necessary line of defence of our country, secondary only to that of our naval and military forces. Again, two articles have appeared in the *Kölnische Zeitung* (March 10 and 11), which criticise our manufacturing and business and military want of method with an unsparing pen. The German writer and many English writers seem to think that we ought to copy Germany. Nobody can feel more than I do the great necessity which exists for reform; but I think that our reform must be far more thorough than anything which can be regarded as a mere copying of Germany; the methods which we adopt must be English methods, invented by Englishmen for Englishmen. If our methods are to help to lead in the future to a history comparable in glory with the history of the past, there must be a great commonsense reform in education in England from top to toe. My friends, Profs. Ayrton and Armstrong, and I have so often pointed out the deficiencies of England in matters which we have carefully studied here and in foreign countries, that I hardly know whether an idea on this subject is my own or one of theirs; I do know, however, that we preach often on this subject, and that we never seem to be much attended to.

One thing that seems to be quite exasperating is that almost all the most important, the most brilliant, the most expensively educated people in England; our poets and novelists; our legislators and lawyers; our soldiers and sailors; our great manufacturers and merchants; our clergymen and schoolmasters, are quite ignorant of physical science; and it may almost be said that in spite of these clever ignorant men, and men like them in other countries, through the agency of a few men who are not ignorant, all the conditions of civilisation are being completely transformed. I do not merely mean here ignorance of the principles of science, I mean also ignorance of all those methods of working which come from experimental and observational scientific training. The great men go occasionally to popular scientific lectures (as they go to the Royal Academy), and they think that they comprehend something of the latest scientific discoveries because they have seen some fireworks and lantern slides; they are genial to scientific men when they meet them at dinner parties; but, in truth, scientific men are as much outside their counsels as sculptors or painters, or musicians or ballet-dancers. Among these great men a few visits to Albemarle Street are sufficient to create a reputation for science. I wish to show that this ignorance of our great men tends to create ignorance in our future leaders; is hurtful to the strength of the nation now, and retards our development in all ways.

These great men really direct the building of ships of war, and the creation of munitions of war; that is, they select the men who have to do these things, and they also lay down the unscientific rules which prevent their selected men from doing their work scientifically.

I will give an example. They order that the building of five line-of-battle ships shall be started immediately. The scientific constructor knows that he ought to throw away—waste—100,000*l.* in making experiments to find out how the older type of ship may be greatly improved. But his superiors have made the rule that for money expended there must be something to look at. Hence no experiments may be made, and the constructor starts at once to expend five millions of pounds on building ships which are nothing like so good as they might be made.

Other examples. For many years huge guns were built of tubes. It was known to the few scientific men who can calculate about such things—the men who are never consulted—that it was not possible to turn and bore those tubes with the accuracy required by the theory. It happens that nature applies a correction to a wrong method of manufacture, and so these guns are not useless. It is quite well known that a little science and expensive experiment would cause the present wire method of manufacture of guns to be discarded for a simpler, quicker, better, cheaper system. The water-tube boilers, so numerous in our Navy, have proved as worthless as the best scientific men thought them from the beginning, and possibly now it is absurdly assumed that all water-tube boilers are useless. The construction of efficient submarine boats was possible thirty years ago. Many electrical and mechanical engineering appliances that might be very useful to an army or navy have never yet been tried under the direction of competent engineers. Above all—and this includes everything—men of scientific training are not chosen for the Government, civil, and naval and military posts where such training is necessary.

If our leaders were merely unscientific—if they were merely like Boers, and had no scientific knowledge—it would not be so bad, for they would probably appoint scientific men to posts in which a knowledge of physical science is needed, and they might accept the opinions of scientific experts. Even if they were like savage chiefs there would possibly be equal chances among all candidates for posts; but, unfortunately, it is as if our leaders possessed great *negative* knowledge of natural science, and as if a man's chances of being appointed to a scientific post, or of having his advice listened to, were in inverse proportion to his scientific qualifications.

Scientific men look around them and see that everything is wrong in the present arrangements, but they also see that it is useless to give advice which cannot be understood by our rulers. And, indeed, I may say that when by accident a scientific man is appointed on a committee, there is a negative inducement for him to do anything.

Many men enter the services by examination. In some cases the examination is supposed to be in science. In truth, the scientific habit of thought, the real study of science, the very fitness of a boy for entrance to the service, would unfit him for passing these abominable unscientific examinations. For some posts—the Royal Artillery and Engineer services, for example—further scientific food is provided by the Government after a man enters. If one wishes to hear how evil this system of pretended education is, let him ask the opinion of some of the professors who are condemned to help in carrying it out. The whole system is foolishness from bottom to top, and the men prepared by the system cannot see how abominable it is even when they are afterwards trying to improve it.

But however harmful the present state of things may be for the Government services, I think that it is much more pernicious for the country at large. We see that the greatest intellects of our time have been developed through an education other than scientific; and as nobody can commend it for the mere knowledge given at school, it is commended for its importance in mental training.

It has been so often asserted by parrots, that many people do really believe that only mere mental training need be given until a boy is sixteen years of age. When one hears such a statement for the hundredth or thousandth time, he sometimes wonders if anybody ever does think for himself. Why, the early period of a boy's life is the time when he is not only getting mental training, but also collecting the largest part of all the knowledge that he ever will possess of the world into which he has come. So great is this stock of facts and theory, that when he looks back upon his life in old age he can hardly find that he has added much to it in the intervening years. Is he a musician in after life? then he certainly learnt his skill, acquired his touch, trained his ear, and learnt thousands of airs in early youth. Is he a poet? it is to his earliest efforts that he looks back most fondly, and it was in his early youth that he learnt off by heart all the poetry that he really knows well in after life. He learns to read and write and cypher with ease and readiness; is this mere training of the mind? This craze for mind-training is really the worst thing that has happened to the hurt of children. It does not seem to be known to the mind-trainer that a child's mind grows most healthily when let alone—when the child is picking up knowledge in his own way. Give a boy a chance of seeing things for himself, and direct him as little as possible. Is there any kind of knowledge likely to be needed by him in after life? let him, when quite young, have some chance of picking up something of it for himself. He learns about people; he cannot help it, as he lives among people.

I take it that whatever kind of knowledge the race has been in the habit of picking up in youth is more easily picked up than any other by a boy himself. A boy takes to thinking for himself so naturally that the greater parts of some vile systems of education seem to be the destruction of this habit. Yes, education often means merely training a boy out of the way he *would* go into the way that we poor creatures think that he *should* go. And hence it is that the boy whose education is neglected, but who has chances of seeing things for himself, has often a much better chance in life than the well-trained prig.

Now there is a kind of knowledge greatly needed in life, that knowledge which is enabling us to fight with and use the powers of nature as they never were fought with or used before our time. The race is not accustomed to picking up this kind of knowledge, and so there is this one case in which artificial help to the child is absolutely necessary. Natural phenomena are complex; let him have a chance of using apparatus that will simplify these phenomena for him. It seems to me that natural science is almost the only study in which instruction from a father or teacher will not obstruct a boy's own natural method of study. And see how many ways of study are offered by it to a boy. Some of the sciences are greatly observational. If he is fond of abstract reasoning, he attacks things from the mathematical side. If he is fond of fireworks, he can attend popular lectures. If he loves to make and fiddle with apparatus, and use it quantitatively, he has an altogether new method of study. He may choose which method he pleases; the study is utterly unlike a series of tasks; he does not get to think of a duty as something disagreeable; and, above all, he is encouraged to think for himself. Instead of constant correction, criticism, and reproof or punishment because he will think for himself, he is encouraged to consider that opinions which he disagrees with are to be criticised by him. If he feels that it is quite hopeless for him to follow abstract reasoning, say about a whole being greater than its part or the ratio of two incommensurables, or justification by faith, we reply to him—Yes, my boy, you have a good healthy mind like 98 per cent. of all English boys; it is quite impossible for us to make a seventy-year-old Alexandrian philosopher of you, thank God! time enough for you to do that for yourself when you have finished your educational course.

I say that this observational and experimental kind of study is almost the only one in which it is possible for a teacher to guide and instruct without doing harm—and it is very important that a boy's studies should be guided. Take the very clever boy who dislikes the study imposed upon him, and who takes earnestly to something else, his own choice, in which he has no guidance. See how he becomes a "crank." A man who might be of the salt of the earth if he could only co-ordinate his opinions with those of other people, a leader among men of thought; he loves to differ from all other people, and wastes a valuable life in disputation.

I know that many readers will find it difficult to consider this question; they will find it impossible to see things from a new point of view. As a rule a man has no point of view of his own, he never thinks for himself except about certain matters that only concern himself. Even a learned man thinks, not on the subject of his learning, but about his special methods of cataloguing his knowledge, and of course it is only from this that he can get any mental enjoyment. The dullest boy thinks a good deal, and even the average man, although thinking for himself has been repressed in him all his life. We ought to call all such people pedants, because they never really think about things of general interest to the world. It is extraordinary how general is the impression of everybody that he really does think for himself and comprehends what he says. At the age of fourteen I wrote an excellent little essay on Chaucer; I recollect now that my knowledge of Chaucer was confined to a few of the well-known extracts.

The opinions of educated young men change with the moon, or rather with the period of publication of the monthly magazines. A mathematical teacher uses the same fallacious logic in some demonstration year after year, and at length finds out his mistake from somebody else. Learning seems to destroy all power to think. From 500 A.D. to 1453 A.D. the scholars of Constantinople, with all the learning of Greece and Rome, produced not one original work.

I think that for a very clever boy any subject of study is good enough, although not so good as natural science. But Sanscrit, Chinese, or any other language and literature, or astrology or divinity, is just as good a medium as Greek or Latin, if all the best men of his own time happen to use the same medium, and if it enables him to come into mental contact with great men. But what of the other 98 per cent. of all boys—the average boys?

The men who frame schemes of education really frame them for boys such as they themselves were. Anybody who cannot follow such a scheme is said to be stupid, and he is so often called stupid that he actually gets to think himself stupid. In this nineteenth century we do not wish, as in the time of Erasmus, to produce merely a few learned men. At all events, if parents pay largely for education, we do not think it fair to send back 98 per cent. of their sons with the contract unfulfilled on our part. Think of 100 boys being sent to a bootmaker who had only one kind of ready-made boot of one size. He sends ninety-eight of the boys back with feet so hurt by trying on that they can never wear anything but slippers all their life after; he keeps their money, and compels the boys and their parents to take all the discredit of the transaction. Christ's curse is on the schoolmaster when he calls a boy a blockhead.

It is a very curious thing that when a boy has been called a dunce a number of times he actually gets to think himself a dunce, and in after life never blames his schoolmaster; he has only praise for the system of education. Men who have never been able to do more than quote tags from the Latin grammar, or get beyond the Asses' Bridge in Euclid, are usually quite enthusiastic about the value of the orthodox education in the training of the mind, and so we find engineers and other illiterate persons advocating classical education. A donkey might just as well brag of the enormous advantage it was to him in having once been kept about a racing stable. But a much more curious thing is the praise given by clever mathematical physicists to the wretched system of teaching of Euclid which wasted their youth. A well-known and exceedingly able and ingenious scientific man praises the school teaching in physics and chemistry which he had as a boy from a certain master of his, and yet everybody who knew master and pupil knows that the pupil became a scientific man in *spite* of, and not through, the teaching of his master. Even if such clever men were right as to suitability of a system of training for themselves, they have no right to assume that it is right for the other 99 per cent. of boys at school.

Classical education gets all the credit that ought to belong to the other kinds of education that usually accompany it. A boy is at a good public school at which healthy, moral, manly training of all kinds is given to the usual manly type of boy. All the best masters are probably good in classics. The boy's own prizes are for classics, because there are not often scholastic prizes for anything else. Success in classics has been always put before him as the highest kind of success. The boys whom he worships are all good in classics. Of course, classics gets the credit for everything, including those things that are good in *spite* of the classics. Even good manners and tact and amiability, and I might almost say good batting and bowling and fielding, are thought to be due to the classics. The defenders of classics are numerous, and miss no chances. A scientific friend of mine, before a royal commission, commended the study of Greek, because the Greek alphabet is so much used in mathematics. Surely for such a purpose Chinese is ever so much more valuable, as there are many more letters. Again, it is said that the study of classics helps one greatly in the study of modern languages. These defenders forget that Russians and Japanese are the best of linguists, and yet they seldom learn any Latin or Greek. It is strange also to find so many English boys, trained for years in Latin and Greek, who seem to find insuperable difficulties in learning a modern language. In any case, I am inclined to think that there is too much inclination to force boys to learn modern languages. Some boys learn easily; for them the study may be good. Others learn with extreme difficulty. Had they not better study something else?

Everybody is aware of the enormous difficulty of introducing a new invention, however valuable, if it involves the "scrapping" of much existing machinery. Thus, electric methods of working the District Railway have not yet been introduced. The comfort of railway passengers everywhere is only slowly being attended to. For this reason electric lighting proceeded slowly in England and quickly in America.

Now all the machinery of a school head master is fitted for the teaching of Latin and Greek. Every master is able to teach Latin well to clever boys, and everything good for mental training for clever boys in such teaching is well known to him. These men with capital so invested look with alarm on every new footing gained by science in schools, and with a wisdom gained by experience they introduce what *they* call science teaching, adopting methods which are such as can only disgust boys and their parents with the new study, and then they point to their want of success as a proof that the study of science affords no good education.

The prospect is very dismal; for the capitalists whom we fight against, whose interests we directly attack, are not only some of the very cleverest men of the country, but they have the ears of nearly all the other clever men.

In the time of Henry VII. the new learning fought and conquered the schoolmen, and England soon became covered with good grammar schools. Then mathematics came gradually in, fighting a hard fight till it has made its way and established itself—not on equality terms, but on terms of sufferance and recognition. To meet modern wants, to equip our men for the fight of to-day, we find that it is absolutely necessary to introduce the study of physical science, and lo! we have opposing us the combined forces of classics and mathematics, each with its own kind of weapon. The weapon of the mathematical pedant is the more dangerous, for he says that he already represents science.

This teaching of pseudo-science in schools has created a manufacture of teachers. At all the universities we are now manufacturing science B.A.'s and B.Sc.'s because there is a new profession where money may be earned by the holder of such a title. This manufacture is called scientific education, and our real scientific men, pleased with the name, pleased at any experiment in scientific education, afraid that if they object there will be no education whatsoever in science, weakly give their countenance to it. To illustrate what I mean:—At the greatest of our universities there is an examination in which experimental physics plays an important part. A friend of mine coaches men for this examination. He tells them: "Listen to my coaching, read the books as I tell you, take care *not* to attend the physics laboratory. For in one day's reading you will get to know all that there is in thirty pages of the book; you may spend a month at the laboratory and you will have gained practically nothing to fit you for any possible kind of examination. The laboratory does not pay." Of course he is right, but if mere learning, if mere knowledge of certain facts, mere power to pass an examination, are what is aimed at, surely there is no scientific education here. My friend asserts that the system by which he earns his living is abominable. The whole thing is so wrong that one wants an earthquake or a fire, one prays for wholesale destruction of the easily working examination machinery.

I remember teaching physics at a school in which the time for science was so limited that only one half-hour's lecture per week could be given to the best men in the school. There were about 100 of them, from the sixth and fifth forms. Some of them are now leaders of English thought. Well, they were actually examined once a fortnight—a paper examination, lasting an hour. Of course, they were not examined on the two lectures; they were really examined on two chapters of the textbook. I am told, and I believe, that in many of the best girls' schools science is supposed to be taught by a teacher reading things from a text-book, the girls taking notes. I should think it an excellent system if girls are required to pass the usual examinations.

Examinations are said to be in mechanics or dynamics, or mathematical physics, or mechanical or civil engineering. They are not; they are fraudulent substitutions of the stupidest kind of mathematics for these sciences.

Assume something or other to be true, that the coefficient of friction is constant, for example, or that a specific heat is constant, and, after covering the paper with easy mathematical exercise work, arrive at mathematic expressions which are as worthless as the mental training is bad. What a wonderful and useful weapon one possesses in mathematics! In the hands of a man like Rankine, or Kelvin or Maxwell, it removes mountains of difficulty. What a stupefying and useless weapon it is in the hands of a skill-less person who cannot think! And our examination systems and methods of education seem framed to cultivate one Kelvin to 10,000 of the pedantic non-thinking users of mathematics.

My theme has been the necessity for a complete change in our system of early education of everybody. The necessity is specially great in the case of the captains of industry. Many people think that if men are to be taught the scientific principles underlying the proper conduct of business or manufacture, it is only necessary to establish Technical Schools for them. When I was young I remember that there were many agricultural colleges in Ireland; they have all but one been failures. Why? Because the entering pupils were not fit to receive instruction. Instead of their having been prepared for instruction by their earlier education, this had done as much as possible to unfit them. We have just this sort of experience in our Technical Colleges. Great boys enter them, and it is difficult to find out what are the scraps of Euclid and mechanics known to these boys on which one has a chance of building technical instruction. It would almost be better to send such boys direct into practical work; they would probably do as well as the average workman; their fathers' influence and money would get them superior positions, and in a country like England they would do as well as their competitors in business. Yet there can be no doubt that it is of the utmost importance to our country, if we are to retain our supremacy in manufactures, that all managers of works, and many of the superior persons employed in large works, should be scientific men, who are also well experienced in the applications of science to their particular industry. But this is not all. I have heard it said, quite truly, that for a great mechanical engineering works what is needed are well-trained managers and foremen, the best labour-saving tools, and an army of negroes as workmen. I am inclined to think that this statement is true; but there is something to be said for the employment of well-educated, intelligent workmen. First, because they are citizens of the country having votes; second, because I believe that all invention comes up from the common workman These men make thousands of observations, which somehow get to their superiors, and it is through these tha inventions come unconsciously; an inventor makes use of ideas received from hundreds of men; the invention is truly his own, but he receives suggestions, unconsciously, from the men who work with their hands at the bench and in the machine shop. If then, I am right, the manufacturing country that depends upon a few good managers and an army of unintelligent slaves will fall as the Roman Empire fell.

Now a workman's intelligence must come through his trade, else he cannot be happy; and if he is unhappy in his trade he cannot be a good citizen or an efficient workman (from the above point of view). At present we pitchfork many boys into a factory, and depend upon the good nature of the workmen for their learning their trade. It used to be that a master taught such a boy his trade as a member of his own family. This personal teaching is no longer possible; but nothing has taken its place. Attendance of apprentices at evening classes after a hard day's work is quite out of the question for all but a small number of very clever young martyrs who sacrifice, not merely their own health and comfort, but the comfort of their families and their duties as citizens. I have myself publicly suggested several times a remedy for this state of things, which has been praised by competent persons, but it seems to me that it is hopeless to expect any adequate remedy to be applied until the influential people of this country are made to see the gravity of the present position.
